#### Abstract

The complexes $\left[\mathrm{M}(\mathrm{C} \wedge \mathrm{P})\left(\right.\right.$ acac- $\left.\left.\mathrm{O}, \mathrm{O}^{\prime}\right)\right]\left[\mathrm{M}=\mathrm{Pt}(\mathbf{1}) \mathrm{Pd}\left(\mathbf{1}^{\prime}\right) ; \mathrm{C} \wedge \mathrm{P}=\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2}-\mathrm{K} \mathrm{C}, \mathrm{P}\right.$; acac $=2,4$-pentanedionato were prepared by the reaction of $[\mathrm{M}(\mathrm{C} \wedge \mathrm{P})(\mu-\mathrm{Cl})]_{2}[\mathrm{M}=\mathrm{Pt}, \mathrm{Pd}]$ with $\mathrm{TI}(\mathrm{acac})$ and fully characterized. The reactions of $\left[\mathrm{Pt}(\mathrm{C} \wedge \mathrm{P})\left(\mathrm{acac}-\mathrm{O}, \mathrm{O}^{\prime}\right)\right](\mathbf{1})$ with equimolar amounts of $\mathrm{HgX}_{2}(\mathrm{X}=\mathrm{I}, \mathrm{Br})$ give the polynuclear complexes $\left[\mathrm{Pt}(\mathrm{C} \wedge \mathrm{P})\left(\text { acac- } \mathrm{O}, \mathrm{O}^{\prime}\right) \mathrm{Hgl}(\mu-\mathrm{I})\right]_{2}$ (2) and $\left[\left\{\mathrm{Pt}(\mathrm{C} \wedge \mathrm{P})\left(\mathrm{acac}-\mathrm{O}, \mathrm{O}^{\prime}\right) \mathrm{HgBr}(\mu-\mathrm{Br})\right\}_{2}\left(\mu-\mathrm{HgBr}_{2}\right)\right]$ (3) containing unsupported Pt -to- Hg donor bonds. In the pentanuclear complex 3, the central mercury atom shows an unexpected square-planar environment, unprecedented for halomercurates(II). The complex $[\mathrm{Pt}(\mathrm{C} \wedge \mathrm{P})-$ (acac-O, $\left.\left.\mathrm{O}^{\prime}\right)\right]$ (1) also reacts with $\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2}\left(\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CF}_{3}\right)$, but in 1:2 molar ratio, to afford the neutral hexanuclear complexes $\left[\mathrm{Pt}(\mathrm{C} \wedge \mathrm{P})\left(\mu-\mathrm{O}_{2} \mathrm{CR}\right)_{2} \mathrm{Hg}\left(\mu^{3}-\mathrm{acac}^{2-}-\kappa \mathrm{C}^{3}, \mathrm{O}\right) \mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}-\kappa \mathrm{O}\right)\right]_{2}[\mathrm{R}$ $=\mathrm{CH}_{3}$ (4), $\left.\mathrm{CF}_{3}(5)\right]$. An X-ray study of 4 revealed that these compounds contain very short platinum-to-mercury donor bonds supported by two carboxylate groups, along with an unusual dimercurated acetylacetone moiety. The reactions of $\left[\mathrm{Pd}(\mathrm{C} \wedge \mathrm{P})\left(\mathrm{acac}-\mathrm{O}, \mathrm{O}^{\prime}\right)\right]\left(\mathbf{1}^{\prime}\right)$ with $\mathrm{HgX}_{2}\left(\mathrm{X}=\mathrm{Br}, \mathrm{I}, \mathrm{CH}_{3} \mathrm{COO}, \mathrm{CF}_{3} \mathrm{COO}\right)$ proceed mainly $\left(\mathrm{X}=\mathrm{Br}, \mathrm{CH}_{3} \mathrm{COO}, \mathrm{CF}_{3} \mathrm{COO}\right)$ with substitution of the acac-0, $\mathrm{O}^{\prime}$ ligand by X from the coordination environment of the palladium center to give the binuclear derivatives $[\mathrm{Pd}(\mathrm{C} \wedge \mathrm{P})(\mu-\mathrm{X})]_{2}\left(\mathrm{X}=\mathrm{Br}, \mathrm{CH}_{3} \mathrm{COO}, \mathrm{CF}_{3} \mathrm{COO}\right)$, hindering the obtention of palladium-mercury compounds by this route.

## Introduction

Metal-metal bonding in heteronuclear complexes containing $\mathrm{d}^{8}$ and $\mathrm{d}^{10}$ metal ions has been known for some years. ${ }^{1} \mathrm{~A}$ rich chemistry has been developed in our

[^0]group on the synthesis of heteronuclear $\mathrm{Pt} \rightarrow \mathrm{Ag}^{2}$ and $\mathrm{Pt} \rightarrow \mathrm{Hg}^{3}$ compounds using mono- or binuclear anionic pentahalophenyl complexes of $\mathrm{Pt}(\mathrm{II})$ as Lewis bases.
More recently we have described the synthesis of neutral $\mathrm{M}(\mathrm{II})$ complexes, $\left[\mathrm{M}(\mathrm{C} \wedge \mathrm{P})\left(\mathrm{S}_{2} \mathrm{C}-\mathrm{Z}\right)\right][\mathrm{M}=\mathrm{Pt}, \mathrm{Pd}$; $\left.\mathrm{C} \wedge \mathrm{P}=\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\mathrm{K} \mathrm{C}, \mathrm{P} ; \mathrm{Z}=\mathrm{NMe}_{2}, \mathrm{OEt}\right],{ }^{4}$ and have also observed, when $\mathrm{M}=\mathrm{Pt}$, their ability to form heteronuclear compounds containing $\mathrm{Pt}-\mathrm{Hg}$ bonds when they react with $\mathrm{Hg}(\mathrm{II})$ salts ( $\mathrm{HgX}_{2}, \mathrm{X}=\mathrm{Br}, \mathrm{I}, \mathrm{CH}_{3} \mathrm{COO}$, $\mathrm{CF}_{3} \mathrm{COO}$ ). These reactions proceed differently depending on the nature of $X$. In some cases ( $\mathrm{X}=\mathrm{Br}, \mathrm{I}$ ) adducts containing unsupported $\mathrm{Pt}^{\mid 1} \rightarrow \mathrm{Hg}$ donor-acceptor bonds are formed; in other cases, the oxidative addition of $\mathrm{HgX}_{2}\left(\mathrm{X}=\mathrm{CH}_{3} \mathrm{COO}, \mathrm{CF}_{3} \mathrm{COO}\right)$ to $\mathrm{Pt}(\mathrm{II})$ takes place, affording compounds containing covalent $\mathrm{Pt}-\mathrm{Hg}$ bonds. ${ }^{5}$ None of these reactions is accompanied by $\mathrm{Pt}-\mathrm{C}$ bond

[^1]cleavage. However, the reactions of the analogous palladium complexes with $\mathrm{HgX}_{2}\left(\mathrm{X}=\mathrm{Br}, \mathrm{CH}_{3} \mathrm{COO}\right.$, $\mathrm{CF}_{3} \mathrm{COO}$ ) proceed with transmetalation, giving rise to binuclear compounds with the $\mathrm{C} \wedge \mathrm{P}$ acting as an unprecedented bridging ligand between the palladium and mercury atoms. Such transmetalation reactions were thought to proceed through electrophilic attack of the mercury salt on the $\mathrm{Pd}-\mathrm{C}\left(\mathrm{sp}^{3}\right)$ bond rather than on the palladium center. ${ }^{5}$
$\beta$-Diketonate complexes usually contain the $\beta$-diketonate bonded via the two oxygen atoms forming a six-membered planar ring. ${ }^{6}$ It has been shown that the central carbon atom on the $\beta$-diketonate ring has nucleophilic character and undergoes metal-carbon bond formation under appropriate conditions. ${ }^{7}$

Taking into account the proven ability of the Hg to form $\mathrm{Pt}-\mathrm{Hg}$ and $\mathrm{C}-\mathrm{Hg}$ bonds, ${ }^{4,5}$ we extended our work to the synthesis of new neutral complexes of $\mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$ containing the same $\mathrm{C} \wedge \mathrm{P}$ group and acetylacetonate as auxiliary ligand. These complexes contain different nucleophilic centers (Pt or Pd, O, C) capable of reacting with mercury salts acting as electrophilic reagents. The synthesis of $[M(C \wedge P)(a c a c)](M=P t, P d)$ and a study of their reactivity toward $\mathrm{HgX}_{2}(X=\mathrm{Br}, \mathrm{I}$, $\mathrm{CH}_{3} \mathrm{COO}, \mathrm{CF}_{3} \mathrm{COO}$ ) form the subject of this work. As a result, we report here the synthesis and the structural characterization of new mixed $\mathrm{Pt}-\mathrm{Hg}$ heteropolynuclear complexes.

## Experimental Section

General Procedures. Elemental analyses were performed on a Perkin-Elmer 240-B microanalyzer. IR spectra were recorded on a Perkin-Elmer 599 spectrophotometer (Nujol mulls between polyethylene plates in the range 200-4000 $\mathrm{cm}^{-1}$ ). NMR spectra were recorded on either a Varian XL-200 or a Varian Unity 300 NMR spectrometer using the standard references. $\left[\mathrm{Pd}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\right.\right.$ acac- $\left.\left.\mathrm{O}, \mathrm{O}^{\prime}\right)\right]$ was pre pared as described elsewhere. ${ }^{8}$
$\left[\mathbf{P t}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\mathrm{K} \mathbf{C}, \mathbf{P}\right\}\left(\right.\right.$ acac- $\left.\left.\mathbf{0}, \mathbf{O}^{\prime}\right)\right]$ (1). To a suspension of [\{Pt\{CH $\left.\left.\left.{ }_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}(\mu-\mathrm{Cl})\right\}_{2}\right](1.0075 \mathrm{~g}$, 0.944 mmol ) in $\mathrm{CHCl}_{3}(30 \mathrm{~mL})$ was added $\mathrm{TI}(\mathrm{acac})(0.5726 \mathrm{~g}$, 1.887 mmol ), and the mixture was refluxed for 3 h . The TICl formed was removed by filtration. After evaporation of the solution to dryness and addition of n-pentane ( 20 mL ) to the residue, a white solid was isolated, 1 ( $0.992 \mathrm{~g}, 88 \%$ ). Anal. Calcd for $\mathrm{C}_{26} \mathrm{H}_{27} \mathrm{O}_{2} \mathrm{PPt}$ : C, 52.26; H, 4.55. Found: C, 52.29; H, 4.41. X-ray Crystal Structure Determinations. Suitable crystals of $\mathbf{3}$ were obtained by slow diffusion of n-hexane into $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solutions of complex $\mathbf{3}$ at $5^{\circ} \mathrm{C}$. Suitable crystals of $\mathbf{4}$ $\mathrm{CHCl}_{3}$ were obtained by slow diffusion of $n$-hexane into $\mathrm{CHCl}_{3}$ solutions of complex 4 at $5^{\circ} \mathrm{C}$.

Crystal data and other details of the structure analyses are presented in Table 1. Crystals were fixed on top of glass or

Table 1. Crystal Data and Structure Refinement Parameters for 3 and $4 \cdot \mathrm{CHCl}_{3}$

quartz fibers and mounted on the diffractometers. Unit cell constants were determined from 25 accurately centered reflections with $22^{\circ}<2 \theta<31.7^{\circ}$ for 3 and 70 reflections in the range $24^{\circ}<2 \theta<26^{\circ}$ for $4 \cdot \mathrm{CHCl}_{3}$. Data were collected using $\omega$ scans for $\mathbf{3}$ and using $\omega / 2 \theta$ scans for $\mathbf{4} \cdot \mathrm{CHCl}_{3}$. Three check reflections were measured at regular intervals, and no loss of intensity was observed for $\mathbf{4} \cdot \mathrm{CHCl}_{3}$, but a decay of $32 \%$ over the period of data collection was observed for 3. The structures were solved by an automated Patterson interpretation routine and developed in the usual series of least-squares refinements and difference Fourier maps. All non-hydrogen atoms were refined with anisotropic displacement parameters. H atoms were added at calculated positions ( $\mathrm{C}-\mathrm{H}=0.96 \AA$ ) and refined with isotropic displacement parameters equal to 1.2 or 1.5 times the equivalent isotropic U's of the corresponding C atoms. The residual peaks of significant height ( $>1 \mathrm{e} / \mathrm{A}^{3}$ ) that were observed in the final difference Fourier map in both complexes were ghosts of the heavy atoms. In the case of $\mathbf{4}$ $\mathrm{CHCl}_{3}$ there are al so some peaks in the sol vent area, indicating some disorder. The refinements were carried out using the program SHELXL-93. ${ }^{9}$

## Results and Discussion

## A. Synthesis and Characterization of $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}{ }^{-}\right.\right.$

 $\left.\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathbf{o} \text {-tolyl })_{2}-\mathrm{KC}, \mathbf{P}\right\}\left(\right.$ acac- $\left.\left.\mathbf{0}, \mathbf{O}^{\prime}\right)\right]$ (1). The reaction of $\left.\left[\left\{\mathrm{Pt}_{\{ } \mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(0-\mathrm{tolyl})_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}(\mu-\mathrm{Cl})\right\}_{2}\right]$ with Tl (acac) in 1:2 molar ratio in refluxing chloroform proceeds with precipitation of TICI and formation of $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\right.\right.$ P (o-tolyl $\left.)_{2}-\mathrm{KC}, \mathrm{P}\right\}\left(\right.$ acac- $\left.\left.\mathrm{O}, \mathrm{O}^{\prime}\right)\right]$ ( $\mathbf{1}$ ), which is obtained from the solution as a white, air-stable solid in a good yield (eq 1).$$
\begin{align*}
& {\left[\left\{\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}(\mu-\mathrm{Cl})\right\}_{2}\right]+} \\
& 2 \mathrm{TI}(\mathrm{acac}) \rightarrow 2 \mathrm{TICl}(\mathrm{~s})+ \\
& \left.\left.2\left[\mathrm{Pt}_{\{ } \mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P} \text { (o-tolyl) }\right)_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\text { acac- } \mathrm{O}, \mathrm{O}^{\prime}\right)\right] \text { (1) } \tag{1}
\end{align*}
$$

Compound $\mathbf{1}$ has been formulated as a squareplanar mononuclear compound (Scheme 1) on the basis of its
elemental analysis and spectroscopic data (IR and NMR) (see Experimental Section).

The $\nu(\mathrm{C}=\mathrm{O})$ stretching vibrations for $\mathbf{1}$ appear at 1591 and $1569 \mathrm{~cm}^{-1}$, at significantly lower energies than those found for the free ligand ( $1720 \mathrm{~cm}^{-1}$ ), and are indicative of $\beta$-diketonate chelation to the metal center. ${ }^{10-13}$ The inequivalence of the two halves of the acac ligand, expected for chelate coordination, is evident from the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of $\mathbf{1}$. Thus, the ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1}$ in $\mathrm{CDCl}_{3}$ at room temperature shows three resonances due to the acac ligand: a singlet at 5.34 ppm due to the $\mathrm{C}^{3} \mathrm{H}$ and two singlets due to the methyl groups. The ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of 1 shows five resonances due to the acac ligand: one at 101.15 ppm corresponding to the $\mathrm{C}^{3}$ atom, which appears as a singlet flanked by the ${ }^{195} \mathrm{Pt}$ satellites ( ${ }^{(3)} \mathrm{Pt}-\mathrm{c}=54.8 \mathrm{~Hz}$ ), two carbonyl resonances close to 184 ppm , and two methyl resonances close to 28 ppm . One of the methyl signals appears as a doublet due to coupling with the trans ${ }^{31}$ P nucleus. These NMR data confirm the structure proposed for compound $\mathbf{1} .^{\text {at, } 14}$

In addition, the $\mathrm{C} \wedge \mathrm{P}$ chelate ligand in $\mathbf{1}$ gives the expected signals in the ${ }^{31} \mathrm{P},{ }^{1} \mathrm{H}$, and ${ }^{13} \mathrm{C}$ NMR spectra (see Experimental Section). A HETCOR experiment was performed on complex $\mathbf{1}$ in order to correctly assign the ${ }^{1} \mathrm{H}$ methyl resonances (Supporting Information).

The analogous palladium compound ( $\mathbf{1}^{\prime}$ ) was prepared similarly to 1. 1 ' has been described previously in the literature. ${ }^{8}$
B. Reactivity of $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\mathrm{K} \mathbf{C}, \mathbf{P}\right\}-\right.$ (acac-0,0')] (1) toward $\mathrm{HgX}_{2}(X=I, B r)$. The

[^2]
## Scheme 1

reactions of $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\right.\right.$ acac- $\left.\left.\mathrm{O}, \mathrm{O}^{\prime}\right)\right]$ (1) with $\mathrm{Hgl}_{2}$ and $\mathrm{HgBr}_{2}$ in 1:1 molar ratio afford the polynuclear complexes $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}-\right.$ (acac-O, O') H gl ( $\mu-\mathrm{I})]_{2}$ (2) and $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2^{-}}\right.\right.$ $\kappa \mathrm{C}, \mathrm{P}\}\left(\right.$ acac- $\left.\left.\left.\mathrm{O}, \mathrm{O}^{\prime}\right) \mathrm{HgBr}(\mu-\mathrm{Br})\right\}_{2}\left(\mu-\mathrm{HgBr}_{2}\right)\right]$ (3) in high yields as air-stable solids (Scheme 1).

Compounds 2 and 3 show similar IR and NMR spectra, but the elemental analyses of $\mathbf{3}$ are indicative of a higher amount of $\mathrm{HgBr}_{2}$ in the complex (see Experimental Section). The X-ray crystal study of 3 confirms the proposed stoichiometry. This means that although the reaction between $\mathbf{1}$ and $\mathrm{HgBr}_{2}$ is carried out in 1:1 molar ratio, the reactants combine with each other in a 2:3 molar ratio (eq 2). However, the remaining quantity of $\mathbf{1}$ is removed completely from the mixture because of its high solubility in diethyl ether, used as precipitating agent for 3.

$$
\begin{gathered}
3\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\text { acac-O,O} \mathrm{O}^{\prime}\right)\right](\mathbf{1})+ \\
3 \mathrm{HgBr}_{2} \rightarrow\left[\left\{\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\text { o-tolyl })_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}-\right.\right. \\
\left.\left.\left(\mathrm{acac}-\mathrm{O}, \mathrm{O}^{\prime}\right) \mathrm{HgBr}(\mu-\mathrm{Br})\right\}_{2}\left(\mu-\mathrm{HgBr} \mathrm{H}_{2}\right)\right](\mathbf{3})+ \\
{\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\text { acac-O}, \mathrm{O}^{\prime}\right)\right] \text { (1) (2) }}
\end{gathered}
$$

In contrast, the reactions between the palladium derivative $\left[\mathrm{Pd}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\right.\right.$ acac- $\left.\left.\mathrm{O}, \mathrm{O}^{\prime}\right)\right]$ ( $\left.\mathbf{1}^{\prime}\right)$ and $\mathrm{HgX}_{2}(\mathrm{X}=\mathrm{I}, \mathrm{Br})$ proceed very differently, as can be seen in Scheme 1. Whereas $\mathrm{Hgl}_{2}$ does not react with $\mathbf{1}^{\prime}, \mathrm{HgBr}_{2}$ does; but the reaction takes place with substitution of the acac- ligand by $\mathrm{Br}^{-}$from the coordination environment of the palladium center and the formation of the binuclear derivative $\left[\left\{\mathrm{Pd}\left\{\mathrm{CH}_{2^{-}}\right.\right.\right.$ $\left.\left.\left.\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}(\mu-\mathrm{Br})\right\}_{2}\right]$. As a result, no mixed palladium-mercury derivatives could be prepared from $\mathbf{1}^{\prime}$ and $\mathrm{HgX}_{2}(\mathrm{X}=\mathrm{I}, \mathrm{Br})$.

Compounds $\mathbf{2}$ and $\mathbf{3}$ have been characterized by elemental analysis and spectroscopic methods (IR and NMR). In addition, the solid-state structure of $\mathbf{3}$ has been unambiguously established by X-ray diffraction analysis.

X-ray Crystal Structure of 3. A drawing of the molecule is shown in Figure 1. Selected bond distances and angles are given in Table 2. As can be seen, the pentanuclear complex 3 can be regarded as being formed by two "Pt $\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\right.$ acac- $\left.\mathrm{O}, \mathrm{O}^{\prime}\right) \mathrm{HgBr}_{2}$ " fragments bridged by an " $\mathrm{HgBr}_{2}$ " unit and related to each other by a center of symmetry.

Figure 1. Molecular structure of $\left[\left\{\mathrm{Pt}(\mathrm{C} \wedge \mathrm{P})\left(\right.\right.\right.$ acac $\left.-\mathrm{O}, \mathrm{O}^{\prime}\right)-$ $\left.\mathrm{HgBr}(\mu-\mathrm{Br})\}_{2}\left(\mu-\mathrm{HgBr}_{2}\right)\right]$ (3). Hydrogen atoms have been omitted for clarity.

${ }^{a}$ Atoms with "a" appended to their names are at $-x,-y+1$, $-z+1$.

Each $\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2}-\mathrm{K} \mathrm{C}, \mathrm{P}\right\}\left(\right.$ acac- $\left.\mathrm{O}, \mathrm{O}^{\prime}\right) \mathrm{HgBr}_{2}$ unit contains one unsupported $\mathrm{Pt} \rightarrow \mathrm{Hg}$ bond. The fivecoordinated Pt atom is located at the center of the base of a square pyramid with the Hg atom in the apical position. The angle between the $\mathrm{Pt}-\mathrm{Hg}$ vector and the perpendicular to the Pt basal plane $[\mathrm{Pt}(1), \mathrm{O}(1), \mathrm{O}(2)$, $\mathrm{P}(1), \mathrm{C}(21)]$ is $7.6(2)^{\circ} .{ }^{15}$ Bond distances and angles in the metallacycle $\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\mathrm{K} \mathrm{C}, \mathrm{P}\right\}$ are simiIar to those observed in other $\mathrm{Pt}(\mathrm{II})$ complexes containing the same group. ${ }^{4}$ The $\mathrm{Pt}-\mathrm{O}$ bond lengths $[\mathrm{Pt}(1)-$ $\mathrm{O}(1)=2.067(10) \AA, \mathrm{Pt}(1)-\mathrm{O}(2)=2.090(9) \AA$ J are similar to those found in $\left(N B u_{4}\right)\left[\left\{\mathrm{Pt}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{2}(\mathrm{acac})\right\}_{2} \mathrm{Ag}\right]^{7 \mathrm{a}}$ and $\left[\mathrm{Pt}_{2} \mathrm{Ag}_{2}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}(\mathrm{acac})_{2}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)_{2}\right],{ }^{16}$ in which each Pt atom is involved in a platinum-to-silver dative bond.
The acac ligand [O(1), O(2), C(22), C(23), C(24), C(25), $\mathrm{C}(26)]$ and the metallacycle $[\mathrm{Pt}(1), \mathrm{P}(1), \mathrm{C}(15), \mathrm{C}(16)$, C(21)] are basically planar and almost coplanar with the basal plane $[\mathrm{Pt}(1), \mathrm{O}(1), \mathrm{O}(2), \mathrm{P}(1), \mathrm{C}(21)]$, the interplanar angles being $1.8(2)^{\circ}$ and $2.8(2)^{\circ}$, respectively. ${ }^{15}$

The $\mathrm{Pt}-\mathrm{Hg}$ distance $[2.8078(11) \AA$ ] and the geometry around the Pt center are similar to those observed in $\left[\left\{2,6-\left(\mathrm{Me}_{2} \mathrm{NCH}_{2}\right)_{2}-\mathrm{C}_{6} \mathrm{H}_{3}\right\} \mathrm{Pt}\left(\mu-\left\{(\mathrm{p}-\mathrm{tol}) \mathrm{NC}(\mathrm{H}) \mathrm{N}\left({ }^{( } \mathrm{Pr}\right)\right\}-\right.\right.$ $\mathrm{HgBrCl}]\left[2.8331(7) \AA \AA_{2}^{17} \text { trans-[( } \mathrm{CH}_{3} \mathrm{NH}_{2}\right)_{2} \mathrm{Pt}(1,5-\mathrm{diMeC})_{2-}$ $\mathrm{Hg}]\left(\mathrm{NO}_{3}\right) \cdot 0.5 \mathrm{H}_{2} \mathrm{O}[2.765(1) \AA]$, ${ }^{18}$ trans-[( $\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)_{2} \mathrm{Pt}(1-$ $\left.\left.\mathrm{MeC}{ }^{-}\right)_{2} \mathrm{HgCl}\left(\mathrm{NO}_{3}\right)\right][2.835(1) \mathrm{A}]$ ], ${ }^{18}$ trans-[( $\left.\mathrm{CH}_{3} \mathrm{NH}_{2}\right)_{2} \mathrm{Pt}(1-$

[^3]$\left.\left.\mathrm{MeC}{ }^{-}\right)_{2} \mathrm{Hg}\right]\left(\mathrm{NO}_{3}\right)_{2}\left[2.785(1) \AA{ }^{2},{ }^{18}\right.$ and $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{O}-\right.\right.$ tolyl) $\left.\left.)_{2}-\mathrm{K}, \mathrm{P}\right\}\left(\mathrm{S}_{2} \mathrm{CNMe} \mathrm{e}_{2}\right) \mathrm{Hgl}(\mu-\mathrm{I})\right]_{2},{ }^{4 \mathrm{~b}}$ for which the $\mathrm{Pt}-$ Hg interaction has been described as a $\mathrm{Pt} \rightarrow \mathrm{Hg}$ donor bond with both metal centers in a formal oxidation state of II. In contrast, the $\mathrm{Pt}-\mathrm{Hg}$ distance is clearly different from those observed in mixed $\mathrm{Pt}-\mathrm{Hg}$ compounds displaying a covalent bond ( $\mathrm{Pt}-\mathrm{Hg}$ ca. $2.5 \AA \AA$ ). ${ }^{19}$ It is noteworthy that, as was observed in $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}\right.\right.$ (otolyl $\left.\left.)_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\mathrm{S}_{2} \mathrm{CNMe} \mathrm{e}_{2}\right) \mathrm{Hgl}(\mu-1)\right]_{2},{ }^{4 \mathrm{~b}}$ which contains the same metallacyde $\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\mathrm{K} \mathrm{C}, \mathrm{P}\right\}$, in complex 3 the $\mathrm{Pt}-\mathrm{Hg}$ bond is not supported by any bridging ligand, despite the presence of two O atoms capable of bonding to the Hg atom.
The Hg atom of each unit $\left\{\mathrm{Pt}_{\{ } \mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2^{-}}\right.$ $\left.{ }_{\kappa} \mathrm{C}, \mathrm{P}\right\}\left(\right.$ acac- $\left.\mathrm{O}, \mathrm{O}^{\prime}\right) \mathrm{HgBr}_{2}$ has a distorted tetrahedral environment formed by one Pt , two bridging, and one terminal Br atoms. The $\mathrm{Hg}(1)-\mathrm{Br}_{\mathrm{t}}$ distance $[\mathrm{Hg}(1)-$ $\operatorname{Br}(3)=2.458(2) \AA$ ] is at the lower limit of the range of terminal $\mathrm{Br}-\mathrm{Hg}$ distances reported in the literature (2.47-2.65 $\AA$ ). ${ }^{20}$ The $\mathrm{Hg}(1)-\mathrm{Br}_{\text {br }}$ distances are very different from each other; while one of them $[\mathrm{Hg}(1)-$ $\operatorname{Br}(1)=3.096(2) \AA]$ is at the high end of the range of $\mathrm{Br}-\mathrm{Hg}$ bridging distances ( $>2.7 \AA$ ), the other one $[\mathrm{Hg}(1)-\mathrm{Br}(2)=2.491(2) \AA]$ is the shortest $\mathrm{Hg}-\mathrm{Br}_{\mathrm{br}}$ distance reported to date. ${ }^{20}$ Unsymmetrical $\mathrm{Hg}_{2}(\mu-\mathrm{Br})_{2}$ bridges are commonly observed in other hal ogenomercuriates. ${ }^{20,21}$

The mercury atom of the $\mathrm{HgBr}_{2}$ unit, $\mathrm{Hg}(2)$, is located at the inversion center of the molecule. $\mathrm{Hg}(2)$ is linearly coordinated by two covalent $\mathrm{Hg}-\mathrm{Br}$ bonds $[\mathrm{Hg}(2)-\mathrm{Br}(1)$ $=\mathrm{Hg}(2)-\mathrm{Br}(1 \mathrm{a})=2.475(2) \AA$ ] and two weak $\mathrm{Hg} \cdots \mathrm{Br}$ bonds $[\mathrm{Hg}(2)-\mathrm{Br}(2)=\mathrm{Hg}(2)-\mathrm{Br}(2 \mathrm{a})=3.006(2) \AA$ A] giving rise to a rhombic-planar geometry. This coordination environment involves bond angles around $\mathrm{Hg}(2)$ between cis bromide atoms very close to $90^{\circ}$. The most common coordination in bromo- and iodomercurates is tetrahedral, but other types of coordination are also observed, such as trigonal, trigonal bipyramidal, or octahedral and are mostly described as heavily distorted. ${ }^{20,21}$ The adduct $\left[\left\{\left(\mathrm{C}_{4} \mathrm{H}_{9}\right)_{3} \mathrm{As}_{2} \mathrm{Hg}_{2} \mathrm{Br}_{4} \cdot \mathrm{HgBr}_{2}\right]^{219}\right.$ has the same stoicheometry as $\mathbf{3}$, but the additional Hg atom (from the $\mathrm{HgBr}_{2}$ unit) shows an octahedral envi-

[^4]
## Scheme 2

$\mathrm{M}=\mathrm{Pt}, \mathrm{R}=\mathrm{CH}_{3}(\mathbf{4}), \mathrm{CF}_{3}(\mathbf{5})$

ronment formed by two covalent $\mathrm{Hg}-\mathrm{Br}$ bonds and additional weak bonds to four bromide atoms from two neighboring $\left[\left\{\left(\mathrm{C}_{4} \mathrm{H}_{9}\right)_{3} \mathrm{As}\right\} \mathrm{HgBr}(\mu-\mathrm{Br})\right]_{2}$ fragments. Thus, as far as we know, complex $\mathbf{3}$ is the first example of bromomercurate(II) containing a mercury atom in a distorted square-planar coordination environment, and it also exhibits the shortest $\mathrm{Hg}-\mathrm{Br}_{\mathrm{br}}$ bond lengths reported to date.

Spectroscopic Behavior of $\mathbf{2}$ and 3. The IR spectra of $\mathbf{2}$ and $\mathbf{3}$ show in each case one absorption due to the $v_{\mathrm{st}}(\mathrm{CO})$ of the acac ligand at lower frequency than the corresponding bond in the starting material, complex 1. This fact indicates that bonding betweeen the Pt and Hg fragments is not through the $\mathrm{C}^{3}$ of the acac ligand but through the metal atoms, ${ }^{6,7 a, 16}$ as it has been unambiguously established from the X-ray study on complex 3.

The NMR spectra of $\mathbf{2}$ and $\mathbf{3}$ in solution show the signals due only to one $\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}-$ (acac-O, $\mathrm{O}^{\prime}$ ) $\mathrm{HgBr}_{2}$ unit, in agreement with the molecular symmetry observed in the crystal for 3. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of both complexes show only one singlet flanked by the ${ }^{195} \mathrm{Pt}$ satellites. The frequencies of these signals are similar, and the ${ }^{195} \mathrm{Pt}-\mathrm{P}$ coupling constants are smaller than those observed in the starting complex 1 (see Experimental Section). As was the case in the complexes $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\mathrm{S}_{2} \mathrm{CZ}\right) \mathrm{HgX}(\mu-\right.$ $X)]_{2}\left(Z=N M e_{2}, O E t ; X=B r, I\right),{ }^{4 b}$ these facts suggest that the Pt and Hg fragments are connected through a Pt -to- Hg donor bond.

The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of $\mathbf{2}$ and $\mathbf{3} \mathrm{in} \mathrm{CDCl}_{3}$ at room temperature $\left(20^{\circ} \mathrm{C}\right)$ also confirm the equivalence of the two halves of the molecules and the interaction of the two metal fragments $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\right.\right.$ P(o-tolyl) $\left.2_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\right.$ acac- $\mathrm{O}, \mathrm{O}^{\prime}$ ), $\mathrm{HgX}_{2}$ ] through the metal atoms, since no important shifts of the $\mathrm{C}^{3}$ and carbonyl resonances are observed when compared to the starting complex 1 (see Experimental Section). ${ }^{7 a, 14,22}$

The similarities of the spectroscopic data of $\mathbf{2}$ and $\mathbf{3}$ imply that in complex 2, as in complex 3, the interaction

[^5]

Figure 2. Molecular structure of $\left[\mathrm{Pt}(\mathrm{C} \wedge \mathrm{P})\left(u-\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{2}-\right.$ $\left.\mathrm{Hg}\left(\mu^{3}-\mathrm{acac}^{2-}-\kappa \mathrm{C}^{3}, \mathrm{O}\right) \mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}-\kappa \mathrm{O}\right)\right]_{2}(4)$. Hydrogen atoms have been omitted for clarity.
between the neutral platinum and mercury fragments takes place through a $\mathrm{Pt}-\mathrm{Hg}$ bond. This observation, along with the elemental analysis of $\mathbf{2}$ leads us to propose for it the molecular structure represented in Scheme 1, which is analogous to the structure of the complexes $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(0 \text {-tolyl })_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\mathrm{S}_{2} \mathrm{CZ}\right) \mathrm{HgX}(\mu-\right.$ $X)]_{2}\left(Z=N M e_{2}, O E t ; X=B r, I\right)$, reported previously. ${ }^{4 b}$
C. Reactivity of $\left[M\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\text { o-tolyl })_{2}-K \mathrm{C}, \mathrm{P}\right\}-\right.$ (acac-0, $\left.\left.0^{\prime}\right)\right]\left[M=P t(1), \mathrm{Pd}\left(1^{\prime}\right)\right]$ toward $\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2}$ ( $\mathbf{R}=\mathbf{C H}_{3}, \mathbf{C F}_{3}$ ). The reactions of $\left[\mathrm{M}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\right.\right.$ tolyl $\left.)_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\right.$ acac- $\left.\left.\mathrm{O}, \mathrm{O}^{\prime}\right)\right]\left[\mathrm{M}=\mathrm{Pt}(\mathbf{1}), \mathrm{Pd}\left(\mathbf{1}^{\prime}\right)\right]$ with $\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2}\left(\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CF}_{3}\right)$ proceed with the displacement of the acac- ligand from the coordination sphere of the metal $(\mathrm{M})$ by the carboxylate groups. Because of the different stabilities of the species initially formed, the resulting derivatives are different when M is Pt or Pd.

The reactions of $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\right.$ (acac$\left.\mathrm{O}, \mathrm{O}^{\prime}\right)$ ] (1) with $\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2}\left(\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CF}_{3}\right)$ in 1:2 molar ratio in methanol at low temperature result in the formation of the neutral hexanudear complexes [Pt-$\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\text { o-tolyl })_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\mu-\mathrm{O}_{2} \mathrm{CR}\right)_{2} \mathrm{Hg}\left(\mu^{3}-\mathrm{acac}^{2-}-\right.$ $\left.\left.\kappa \mathrm{C}^{3}, \mathrm{O}\right) \mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}-\kappa \mathrm{O}\right)\right]_{2}\left[\mathrm{R}=\mathrm{CH}_{3}\right.$ (4), $\mathrm{CF}_{3}$ (5)], as is represented in Scheme 2. The molecular structure of 4 (X-ray diffraction, Figure 2) will be discussed in detail later. During the course of the reaction, complexes 4 and 5 decompose to give $\left[\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tol yl })_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}(\mu-\right.$ $\left.\left.\mathrm{O}_{2} \mathrm{CR}\right)\right]_{2}\left(\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CF}_{3}\right)$ and $\left[\left\{\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}-\kappa \mathrm{O}\right)\right\}_{2}\left(\mu^{2}-\mathrm{acac}^{2-}-\right.\right.$

${ }^{\text {a }}$ Atoms with "a" appended to their names are at $-x,-y+1$, $-z+1$.
$\left.\left.{ }_{\kappa} \mathrm{C}^{3}\right)\right]^{23}\left(\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CF}_{3}\right)$ (Scheme 2), which could be separated from the reaction mixture because of their very low solubility in methanol and chloroform, respectively. When the reactions between 1 and $\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2}$ ( $\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CF}_{3}$ ) were carried out in 1:1 molar ratio, complexes $\mathbf{4}$ and $\mathbf{5}$ were formed as well, but they were obtained with the starting complex, 1, as impurity. The new complexes, 4 and 5 , have been characterized by elemental analysis and spectroscopic methods (IR and NMR). The solid-state structure of 4 has been established by X-ray diffraction analysis.
The reactions of the palladium derivative, $\mathbf{1}^{\prime}$, with $\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2}\left(\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CF}_{3}\right)$ in methanol at low temperature render $\left[\mathrm{Pd}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-toly } \mathrm{y})_{2}-\mathrm{K} \mathrm{C}, \mathrm{P}\right\}\left(u-\mathrm{O}_{2} \mathrm{CR}\right)\right]_{2}$ $\left(\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CF}_{3}\right)^{24}$ and $\left[\left\{\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}-\kappa \mathrm{O}\right)\right\}_{2}\left(\mu^{2}-\mathrm{acac}^{2-}-\kappa \mathrm{C}^{3}\right)\right]^{23}$ ( $\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CF}_{3}$ ) (Scheme 2) when the reactions are carried out in 1:2 or in 1:1 molar ratio. These compounds are anal ogous to those obtained as byproducts in the syntheses of the Pt derivatives $\mathbf{4}$ and $\mathbf{5}$. Because of that, we think that intermediate species (A, B) similar to 4 and $\mathbf{5}$ are initially formed, but that the poor ability of palladium(II) to form $\mathrm{Pd} \rightarrow \mathrm{Hg}$ bonds makes the intermediates very unstable and they decomposequickly to give the final products in high yield.

X-ray Crystal Structure of 4. A drawing of the molecule is shown in Figure 2. Selected bond distances and angles are given in Table 3. As can be seen, complex 4 is a hexanuclear species of platinum and mercury formed by two trinuclear units $\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o}-\mathrm{tolyl})_{2^{-}}\right.$ $\left.{ }_{\kappa} \mathrm{C}, \mathrm{P}\right\}\left(\mu-\mathrm{O}_{2} \mathrm{CR}\right)_{2} \mathrm{Hg}\left(\mu^{3}-\mathrm{acac}^{2-}{ }^{2} \mathrm{C}^{3}, \mathrm{O}\right) \mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}-\kappa \mathrm{O}\right)$ related to each other by a center of symmetry and connected by one oxygen atom of the acac ${ }^{2-}$ bridging ligand.

In each unit the five-coordinated Pt atom is located at the center of the base of a distorted square pyramid with the Hg atom in the apical position. The angle between the $\mathrm{Pt}-\mathrm{Hg}$ vector and the perpendicular to the

[^6]Pt basal plane $[\mathrm{Pt}(1), \mathrm{O}(1), \mathrm{O}(3), \mathrm{P}(1), \mathrm{C}(7)]$ is only 7.2(1) ${ }^{\circ} .{ }^{15}$ The base of the pyramid is not rigorously planar, with the atoms $\mathrm{C}(7)$ and $\mathrm{O}(1)$ away from the best least-squares plane by 0.124 and $0.147 \AA$, respectively. Angles around the platinum between cis ligands deviate from the expected value $\left(90^{\circ}\right)$, especially the angle $P(1)-$ $\mathrm{Pt}(1)-\mathrm{O}(3)$, with a value of $100.4(2)^{\circ}$. The Pt-P, ${ }^{4} \mathrm{Pt}-$ $\mathrm{C},{ }^{4}$ and $\mathrm{Pt}-\mathrm{O}^{19 a, b, 25}$ bond lengths are similar to those found in other complexes containing the same kinds of ligands. The $\mathrm{Pt}-\mathrm{O}$ bond lengths $[\mathrm{Pt}(1)-\mathrm{O}(1)=2.071(7)$ $\AA, \operatorname{Pt}(1)-O(3)=2.149(7) \AA$ ] show the higher trans influence of $C$ with respect to $P$. ${ }^{25,26}$

The geometry around the Pt atom is similar to that observed in other complexes for which the $\mathrm{Pt}-\mathrm{Hg}$ interaction has been described as a Lewis acid-base type. $4,17,18$ However, the $\mathrm{Pt}(1)-\mathrm{Hg}(1)$ bond length [2.6498(9) $\AA$ ] is clearly shorter than those observed in this kind of complex, but similar to that observed in the complex $\left[\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{R}-\mathrm{Pt}-\mathrm{Hg}-\mathrm{R}\right][\mathrm{Pt}-\mathrm{Hg}=2.637(1) \mathrm{A}]{ }^{19 \mathrm{c}}$ in which the $\mathrm{Pt}^{\prime}$ and $\mathrm{Hg}^{\prime}$ centers are covalently bonded. These facts indicate that the $\mathrm{Pt}-\mathrm{Hg}$ interaction is most likely a very strong Pt-to-Hg dative bond with both metals in a formal oxidation state of 2 . Two acetate groups bridge $\mathrm{Pt}(1)$ and $\mathrm{Hg}(1)$, but they seem not to be responsible for the short $\mathrm{Pt}-\mathrm{Hg}$ distance in light of the numerous binuclear complexes of transition elements with double carboxylate bridges and with nonbonded intermetallic separations (ca. $3 \AA \AA$ ). ${ }^{27,28}$ These two bridging acetate groups are asymmetrically bonded, with the $\mathrm{Pt}-\mathrm{O}$ bond distances $[\mathrm{Pt}(1)-\mathrm{O}(1)=2.071(7) \AA, \mathrm{Pt}(1)-$ $\mathrm{O}(3)=2.149(7) \AA$ A clearly shorter than $\mathrm{Hg}(1)-\mathrm{O}[\mathrm{Hg}(1)-$ $\mathrm{O}(2)=2.533(8) \AA, \mathrm{Hg}(1)-\mathrm{O}(4)=2.426(8) \AA \mathrm{J}$. The two fragments $\mathrm{Pt}(1)\left(u-\mathrm{O}_{2} \mathrm{CCH}_{3}\right) \mathrm{Hg}(1)$ show distortions from planarity. ${ }^{15}$ The best least-squares planes calculated for these fragments are perpendicular to each other [interplanar angle, $\left.93.5(1)^{\circ}\right]$, and they are also nearly perpendicular to the basal plane, with the angle between $\mathrm{Pt}(1), \mathrm{O}(1), \mathrm{C}(22), \mathrm{O}(2), \mathrm{Hg}(1)$, and the basal plane being $92.9(2)^{\circ}$ and the angle between $\mathrm{Pt}(1), \mathrm{O}(3), \mathrm{C}(24), \mathrm{O}(4)$, $\mathrm{Hg}(1)$, and the basal plane being $83.2(1)^{\circ}$.

The four-coordination environment around $\mathrm{Hg}(1)$ is completed by the $\mathrm{C}^{3}$ atom of a dianionic acac group [ $C(26)$ ]. The $\mathrm{Hg}(1)-\mathrm{C}(26)$ distance [2.157(11) $\AA$ ] is similar to those observed in other complexes containing $\mathrm{Hg}-\mathrm{C} \sigma$ bonds. $3,4 \mathrm{~b}, 19 \mathrm{c}-\mathrm{f}, 29 \mathrm{Hg}(1)$ has a very distorted tetrahedral environment, with the bond angles around $\mathrm{Hg}(1)$ ranging from $76.3(2)^{\circ}$ to $159.2(3)^{\circ}$. The angles $\mathrm{Pt}(1)-\mathrm{Hg}(1)-\mathrm{O}(2)\left[76.3(2)^{\circ}\right]$ and $\mathrm{Pt}(1)-\mathrm{Hg}(1)-\mathrm{O}(4)$ [78.2(2) ${ }^{\circ}$ ] are rather acute, but both are similar to that found in the complex $\left[\left(2-\mathrm{Me}_{2} \mathrm{NCH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}\right)_{2}\left(\mathrm{MeCO}_{2}\right) \mathrm{PtHg}-\right.$ $\left.\left(\mathrm{O}_{2} \mathrm{CMe}\right)\right]\left[80.4(2)^{\circ}\right]^{199, \mathrm{~b}} \mathrm{~A}$ noteworthy feature of complex 4 is the presence of the dianionic acac ${ }^{2-}$ ligand, which bridges two mercury atoms $[\mathrm{Hg}(1), \mathrm{Hg}(2)]$ through its central carbon [C(26)]. As far as we know, only one compound, $\left[\{\mathrm{HgCl}\}_{2}\left(u^{2}-\mathrm{acac}^{2-}-\kappa \mathrm{C}^{3}\right)\right], 29$ showing this unusual coordination mode for the acac ${ }^{2-}$ ligand has been

[^7]reported to date. Atom $\mathrm{C}(26)$ is bonded to four atoms [Hg(1), Hg(2), C(27), C(29)], displaying a tetrahedral environment. The $\mathrm{Hg}(1)-\mathrm{C}(26)-\mathrm{Hg}(2)$ angle [98.5(4) ${ }^{\circ}$ ] shows the largest deviation from the ideal tetrahedral value. The distance $\mathrm{C}(26)-\mathrm{Hg}(2)[2.110(19)$ $\AA \AA$ ] is very similar to $\mathrm{C}(26)-\mathrm{Hg}(1)$ [2.157(11) $\AA$ ] and to that observed in other complexes containing $\mathrm{Hg}-\mathrm{C}$ $\sigma$ bonds. ${ }^{3,4 b, 19 c-f, 29}$

The atom $\mathrm{Hg}(2)$ is bonded to $\mathrm{C}(26)$ of the $\mathrm{acac}^{2-}$ ligand, to $\mathrm{O}(7)$ of a monodentate acetate ligand, and to $\mathrm{O}(6 \mathrm{a})$ from the $\mathrm{acac}^{2-}$ ligand of the second $\mathrm{Pt}\left\{\mathrm{CH}_{2}-\right.$ $\left.\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}\left(\mu-\mathrm{O}_{2} \mathrm{CR}\right)_{2} \mathrm{Hg}\left(\mu^{3}-\mathrm{acac}^{2-}-\right.$ $\left.\kappa \mathrm{C}^{3}, \mathrm{O}\right) \mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}-\kappa \mathrm{O}\right)$ unit. $\mathrm{Hg}(2)$ shows a T-shaped coordination environment with two short distances to $C(26)[2.110(10) \AA \AA$ and $O(7)[2.104(9) \AA \AA]$ and a longer one to O(6a) [2.654(9) $\AA$ ]. The angles around $\mathrm{Hg}(2)$ are similar to those observed in other mercury complexes showing the same coordination envi ronment. ${ }^{19 a, b, 30}$ The distance $\mathrm{Hg}(2)-\mathrm{O}(7)$ is similar to those observed in other complexes containing mercury bonded to a monodentate acetate group, such as $\left[\left(2-\mathrm{Me}_{2} \mathrm{NCH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}\right)_{2}-\right.$ $\left.\left(\mathrm{MeCO}_{2}\right) \mathrm{PtHg}\left(\mathrm{O}_{2} \mathrm{CMe}\right)\right]\left[\mathrm{Hg}-\mathrm{O}=2.10(1) \AA \AA^{19 a, b} \mathrm{C}_{6} \mathrm{H}_{5}{ }^{-}\right.$ $\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CMe}\right)[\mathrm{Hg}-\mathrm{O}=2.11(4) \AA]^{31}$ and $\left[\mathrm{Pd}\left(\mathrm{S}_{2} \mathrm{CNMe}\right)_{2}\right)-$ $\left.\left\{\mu-\mathrm{P}(\text { o-tolyl })_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{CH}_{2}\right\}\left(\mu-\mathrm{O}_{2} \mathrm{CCH}_{3}\right) \mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)\right][\mathrm{Hg}-$ $\mathrm{O}=2.120(5) \AA] .{ }^{5}$ The $\mathrm{Hg}(2)-\mathrm{O}(6 \mathrm{a})$ bond distance [2.654(9) $\AA$ ] is very long although within the range of distances observed for $\mathrm{Hg}-\mathrm{O}$ bonds (2.07-2.666 $\AA$ ). ${ }^{32}$

Spectroscopic Behavior of 4 and 5. The NMR spectra of $\mathbf{4}$ and $\mathbf{5}$ in solution show only the signals due to one trinuclear unit $\mathrm{Pt}\left\{\mathrm{CH}_{2}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\kappa \mathrm{C}, \mathrm{P}\right\}(\mu-$ $\left.\mathrm{O}_{2} \mathrm{CR}\right)_{2} \mathrm{Hg}\left(\mu-\mathrm{acac}^{2-}-\kappa \mathrm{C}^{3}\right) \mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}-\kappa \mathrm{O}\right)$.

The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of both complexes show only one singlet flanked by the ${ }^{195} \mathrm{Pt}$ satellites. For complex 4 the singlet is also flanked by two satellites due to the coupling ${ }^{199} \mathrm{Hg}-\mathrm{P}(\mathrm{I}=1 / 2,16.8 \%)$, which means that the platinum-mercury bond is present in solution. The value of ${ }^{2} \mathrm{~J} \mathrm{Hg}-\mathrm{P}(111.8 \mathrm{~Hz})$ is in agreement with the cis disposition of the two groups relative to the platinum atom. ${ }^{33}$ The ${ }^{1} \mathrm{H}$ NMR spectra of both complexes and the ${ }^{19} \mathrm{~F}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of 5 show the signals corresponding to one $C \wedge P$ group, to the acac ${ }^{2-}$ ligand, and to three inequivalent carboxylate groups (see Experimental Section). In complex 4, seven methyl groups are present. The assignments of these signals to the positions found in the spectrum were done with the help of HETCOR and NOE experiments (Supporting Information). It should be noted that the two diasterotopic $\mathrm{COCH}_{3}$ groups of the acac ${ }^{2-}$ ligand are isochronous. The coincidence in the frequency of the methyl hydrogen atoms indicates that all of them have very similar chemical environments. Because of that, it is reasonable to conclude that in sol ution the equivalence of the two trinudear fragments is more probably due to the breaking of the interaction $\mathrm{Hg} \cdot \cdots \mathrm{O}\left(\mathrm{acac}^{2-}\right)$ than to the symmetry of the hexanuclear molecules. The other ${ }^{1} \mathrm{H}$ and ${ }^{19} \mathrm{~F}$ NMR data are those expected on the

[^8]basis of the solid-state structure of 4 as well as for the trinuclear fragments probably present in solution and merit no further comment.
The ${ }^{13} \mathrm{C}$ NMR signals of the acac derivatives provide very useful structural information. The ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of complex 4 shows, at room temperature, an important downfield shift of the carbonyl resonances when compared to complexes $\mathbf{1}, \mathbf{2}$, or $\mathbf{3}$. These shifts can be understood as the result of a high keto character of the acac ligand in this complex, in agreement with its solid-state structure. ${ }^{7 a}$ U nfortunately, the signal due to the $\mathrm{C}^{3}$ atom cannot be observed in the spectrum. The scarce solubility of 5 and the presence of $F$ atoms in the complex hindered the observation of relevant ${ }^{13} \mathrm{C}$ NMR signals corresponding to the $\mathrm{acac}^{2-}$ and $\mathrm{CF}_{3} \mathrm{COO}^{-}$ groups.

## Conclusion

In this report we describe the reactivity between $\left[\mathrm{M}(\mathrm{C} \wedge \mathrm{P})\left(\right.\right.$ acac- $\left.\left.\mathrm{O}, \mathrm{O}^{\prime}\right)\right]\left[\mathrm{M}=\mathrm{Pt}(\mathbf{1}), \mathrm{Pd}\left(\mathbf{1}^{\prime}\right) ; \mathrm{C} \wedge \mathrm{P}=\mathrm{CH}_{2^{-}}\right.$ $\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{P}(\mathrm{o} \text {-tolyl })_{2}-\kappa \mathrm{C}, \mathrm{P}$; acac $=2,4$-pentanedionato] and $\mathrm{HgX}_{2}\left(\mathrm{X}=\mathrm{I}, \mathrm{Br}, \mathrm{CH}_{3} \mathrm{COO}, \mathrm{CF}_{3} \mathrm{COO}\right)$. The results show once again the different behavior between platinum and palladium and al so between the mercury salts probed.

When $M=P t$, the electrophilic attack of the $\mathrm{Hg}(\mathrm{II})$ salt $\mathrm{HgX}_{2}(\mathrm{X}=\mathrm{I}, \mathrm{Br})$ takes place at the metal center instead of at $\mathrm{C}^{3}$ of the acac ligand, affording the compounds $\left[\mathrm{Pt}(\mathrm{C} \wedge \mathrm{P})\left(\mathrm{acac}-\mathrm{O}, \mathrm{O}^{\prime}\right) \mathrm{Hgl}(\mu-\mathrm{I})\right]_{2}(\mathbf{2})$ and $[\{\mathrm{Pt}(\mathrm{C} \wedge \mathrm{P})-$ (acac- $\left.\left.\left.\mathrm{O}^{\prime} \mathrm{O}^{\prime}\right) \mathrm{HgBr}(\mu-\mathrm{Br})\right\}_{2}\left(\mu-\mathrm{HgBr}_{2}\right)\right]$ (3). The binding between the metal fragments, as established in the crystal structure of 3, is through a direct Pt-to-Hg donor bond not supported by any bridging ligand. In compound 3 both Pt centers show a square-pyramidal coordination geometry with the Hg atom in the apical position. The Hg atoms bonded to Pt show distorted tetrahedral environments, common in $\mathrm{Hg}(\mathrm{II})$ derivatives with the stoichiometry $[\mathrm{HgXL}(\mu-\mathrm{X})]_{2}$. Also, $\mathbf{3}$ contains a third Hg atom which is bonded to four Br atoms in an unexpected square-planar geometry, unprecedented for halomercurates(II).

In light of the recently observed reactions between [Ni(tmtaa)] and $\mathrm{HgBr}_{2}$ to give [Ni(tmtaa) HgBr$]_{2^{-}}$ $\left[\mathrm{Hg}_{2} \mathrm{Br}_{6}\right]\left[\mathrm{H}_{2}\right.$ tmtaa $=5,14$-di hydro-6,8,15,17-tetramethyldibenzo[b,i][1,4,8,11]tetraazacyclotetradecine), in which the Hg atom is bonded to the central carbon of the sixmembered $\beta$-diiminate chelate rings, ${ }^{34}$ and considering the less nudeophilic character of Pd with respect to Pt, in the reactions between $\left[\mathrm{Pd}(\mathrm{C} \wedge \mathrm{P})\left(\mathrm{acac}-\mathrm{O}, \mathrm{O}^{\prime}\right)\right]\left(\mathbf{1}^{\prime}\right)$ and $\mathrm{HgX}_{2}(\mathrm{X}=\mathrm{I}, \mathrm{Br})$ we expected to obtain mixed $\mathrm{Pd} / \mathrm{Hg}$ compounds with the metal fragments connected through the nudeophilic central carbon of the $\beta$-diketonatering. However, the compounds $[\mathrm{Pd}(\mathrm{C} \wedge \mathrm{P})(u-\mathrm{X})]_{2}(\mathrm{X}=\mathrm{Br}, \mathrm{I})$ were obtained, which result from the substitution of acac- by $\mathrm{X}^{-}$from the coordination environment of the Pd center.

The complex $\left[\mathrm{Pt}(\mathrm{C} \wedge \mathrm{P})\left(\right.\right.$ acac- $\left.\left.\mathrm{O}^{\prime} \mathrm{O}^{\prime}\right)\right](\mathbf{1})$ al so reacts with $\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2}\left(\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CF}_{3}\right)$ but in 1:2 molar ratio to give the neutral hexanuclear complexes $\left[\mathrm{Pt}(\mathrm{C} \wedge \mathrm{P})\left(\mu-\mathrm{O}_{2} \mathrm{CR}\right)_{2} \mathrm{Hg}\right.$ -$\left(\mu^{3}-\right.$ acac $\left.\left.^{2-}-\kappa \mathrm{C}^{3}, \mathrm{O}\right) \mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}-\kappa \mathrm{O}\right)\right]_{2}\left[\mathrm{R}=\mathrm{CH}_{3}(4), \mathrm{CF}_{3}(5)\right]$. The structures of $\mathbf{4}$ and 5 imply that displacement of the acac ligand from 1 by the carboxylate groups of one $\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2}$ unit followed by deprotonation of its central

[^9] 1997, 2537.
carbon by another $\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2}$ unit occurs during complex formation. It is worthwhile to note that in compound 4 the $\mathrm{Pt}-\mathrm{Hg}$ bond distance [2.6498(9) $\AA$ ] is extremely short considering that the metal - metal bond is better described as a $\mathrm{Pt} \rightarrow \mathrm{Hg}$ donor bond with both metals in a formal oxidation state of II. Although the ability of $\mathrm{Hg}(\mathrm{II})$ salts to activate $\mathrm{C}-\mathrm{H}$ bonds from carbonyl compounds is well known, ${ }^{35}$ compound 4 is only the second example, characterized by X-ray diffraction, of a $\mu^{2}-\operatorname{acac}^{2-}-\kappa \mathrm{C}^{3}$ ligand, and the first with this ligand asymmetrically dimercurated.

The reactions of $\left[\mathrm{Pd}(\mathrm{C} \wedge \mathrm{P})\left(\mathrm{acac}-\mathrm{O}, \mathrm{O}^{\prime}\right)\right]\left(\mathbf{1}^{\prime}\right)$ with Hg $\left(\mathrm{O}_{2} \mathrm{CR}\right)_{2}\left(\mathrm{R}=\mathrm{CH}_{3}, \mathrm{CF}_{3}\right)$ seem to proceed similarly. However, the poor ability of palladium(II) to form Pd $\rightarrow \mathrm{Hg}$ donor bonds, which is reflected in the absence of $\mathrm{Pd} \rightarrow \mathrm{Hg}$ complexes, $5,36,46$ leads to rapid decomposition of the first products formed, presumably analogous to
