ABSTRACT

Cancer is one of the deadliest diseases worldwide. Chemotherapy remains one of the frequently applied treatment modalities in the clinics. However, as the currently applied agents are associated with severe side effects, scientists are searching for novel chemotherapeutic drugs. Within the last decades, Cu(II) polypyridine complexes have received increasing attention as potential anticancer drug candidates. Herein, the biological activity of terminally functionalised mono- and bis-coordinated Cu(II)-2,2':6',2''-terpyridine complexes have been investigated. The bis-coordinated compounds were found to have a cytotoxic effect in the nanomolar range in human adenocarcinomic alveolar basal epithelial cells. Promisingly, the complexes were equally active in the corresponding cisplatin resistant cell line, indicating that they could potentially be useful for the treatment of drug resistant tumours.

HIGHLIGHTS

- Synthesis of terminally functionalised Cu(II) polypyridine of the type $[\text{Cu}(2,2':6',2''\text{-terpyridine})(\text{Cl})_2]$ and $[\text{Cu}(2,2':6',2''\text{-terpyridine})_2][\text{NO}_3]_2$.
- Single crystal X-ray analysis of metal complexes.
- Biological evaluation revealed cytotoxicity of lead compounds in the nanomolar range against human adenocarcinomic alveolar basal epithelial cells.
- Effective in drug resistant cancer cell line.

GRAPHICAL ABSTRACT

1. INTRODUCTION

Cancer remains one of leading causes of death worldwide as demonstrated by the alarming numbers published by World Health Organisation (WHO) over the last decades.[1] As treatment modalities, chemotherapy is commonly applied in the clinics in combination with radiotherapy, immunotherapy and surgery to circumvent the limitations of each treatment and overall improve the chances of eradication of the tumour and therefore survival of the patient.[2]

To date, the platinum based agents cisplatin, oxaliplatin and carboplatin are clinically applied in more than 50% of chemotherapeutic treatments worldwide.[3, 4] Despite their enormous success, these compounds are not ideal and associated with numerous side effects including nerve and kidney damage, nausea, vomiting, and bone marrow suppression. More worryingly, the number of resistant cancers is increasing, limiting the application of these compounds.[5-8] To tackle this issue, scientists from all over the world are searching for novel chemotherapeutic agents. While the majority of investigated metal complexes are based on rare transition metals, it would be very interesting to develop compounds based on cheap and abundant metals.[9-16]

Among other investigated metals, copper containing compounds are receiving increasing attention due their bioavailability and biocompatibility. The possibility of the reversible change of the oxidation state of the Cu(I)/Cu(II) couple under physiological conditions is appealing and has promoted the development of metal complexes with an active redox chemistry within cancerous cells. While Cu(II) polypyridine complexes have shown to interact with DNA, they were found to oxidatively cleave the phosphodiester bond through the generation of reactive oxygen species. These effects can cause DNA strand breaks and ultimately trigger cell death.[17-19] The first example of such compounds was the $[\text{Cu}(\text{1,10-phenanthroline})_2]^{2+}$ complex, which was found to cleave DNA of Escherichia coli bacteria.[20] Based on these attractive properties, Cu(II) polypyridine complexes are receiving increasing attention as artificial nucleases as well as potential anticancer candidates.[21-26] It is important to note, that two of such compounds, referred to as Casiopeinas[®], are currently investigated in clinical trials.[27, 28] Further the complex diacetylbis(4-methylthiosemicarbazonato)copper(II), also abbreviated as copper-ATSM, is under investigation in clinical trials for the treatment of motor neurone disease.[29, 30]

As a class of compounds with particular interest, complexes of the type $[\text{Cu}(2,2':6',2''\text{-terpyridine})(\text{Cl})_2]$ have been studied. The terminal extension of the ligand with piperidine, bis(2-pyridylmethyl)amine[31, 32], naphthalene[33], anthracene[34] as well as diverse substituted phenyl groups[35] including their multinuclear complexes have generated cytotoxic

agents against various cancer cell lines. Worthy of note, the naphthalene derivative with a labile nitrate and water molecule instead of chloride ligands, was also found to be cytotoxic against cancerous cells.[36] The vast majority of these complexes demonstrated to strongly bind to DNA through an intercalative mode. While being able to efficiently cleave DNA, the compounds were found to be cytotoxic in the low micromolar to nanomolar range, making this class of compounds interesting candidates as anticancer agents.

Considering these promising results, herein, a series of terminally functionalised complexes of the type $[\text{Cu}(2,2':6',2''\text{-terpyridine})(\text{Cl})_2]$ **1-6** and $[\text{Cu}(2,2':6',2''\text{-terpyridine})_2][\text{NO}_3]_2$ **7-12** were synthesised and their cytotoxicity towards cancer cells investigated. We note that during the writing-up of this article, compounds **2** and **8** (with perchlorate as counter ions) were reported as cytotoxic agents against ovarian carcinoma cells by Gamez and co-workers. This study indicated that these compounds strongly interact with DNA and trigger cell death by apoptosis.[33] The compounds reported in our work were synthesised by complexation of the functionalised 2,2':6',2''-terpyridine derivative with CuCl_2 or $\text{CuNO}_3 \cdot x\text{H}_2\text{O}$. Several complexes were also characterised by single crystal X-ray crystallography. The bis-coordinated complexes were found to be cytotoxic in the nanomolar range in adenocarcinomic human alveolar basal epithelial (A549) cells. Promisingly, the Cu(II) complexes were found to be toxic in the corresponding cisplatin resistant cell line, making them potentially interesting as anticancer agents against drug resistant tumours.

2. EXPERIMENTAL SECTION

2.1. Materials

All chemicals were obtained from commercial sources and used without further purification. Solvents were dried over molecular sieves if necessary. The substituted 2,2':6',2''-terpyridine ligands (terpy-X): 4'-chloro-2,2':6',2''-terpyridine (terpy-Cl)[37], 4'-bromo-2,2':6',2''-terpyridine (terpy-Br)[38], 4'-methoxy-2,2':6',2''-terpyridine (terpy-OMe)[39], 4'-carboxy-2,2':6',2''-terpyridine (terpy-COOH)[40], 4'-dimethylamino-2,2':6',2''-terpyridine (terpy-NMe₂)[41] were synthesised as previously reported.

2.2. Instrumentation and methods

ESI-MS experiments were carried out using a LTQ-Orbitrap XL from Thermo Scientific (Thermo Fisher Scientific) and operated in positive ionization mode, with a spray voltage at 3.6 kV. No Sheath and auxiliary gas was used. Applied voltages were 40 and 100 V for the ion transfer capillary and the tube lens, respectively. The ion transfer capillary was held at 275 °C. Detection was achieved in the Orbitrap with a resolution set to 100,000 (at m/z 400) and a m/z range between 150-2000 in profile mode. Spectrum was analyzed using the acquisition software XCalibur 2.1 (Thermo Fisher Scientific). The automatic gain control (AGC) allowed accumulation of up to $2 \cdot 10^5$ ions for FTMS scans, maximum injection time was set to 300 ms and 1 μ scan was acquired. 10 μ L was injected using a Thermo Finnigan Surveyor HPLC system (Thermo Fisher Scientific) with a continuous infusion of methanol at $100 \mu\text{L} \cdot \text{min}^{-1}$. Infrared (IR) spectra (w= weak, m=medium, s=strong, br=broad) were measured with a Nicolet 6700 FTIR spectrometer (Thermo Scientific). Elemental microanalyses were performed on a Thermo Flash 2000 elemental analyser.

2.3. Synthesis

General procedure for the synthesis of $[\text{Cu}(\text{terpy-X})(\text{Cl})_2]$:

CuCl_2 (40 mg, 0.30 mmol) was dissolved in 20 mL of dry methanol under N_2 atmosphere. A solution of the terpy-X ligand (70-83 mg, 0.30 mmol) in dry methanol/dichloromethane (1:1, 20 mL) was added dropwise. The mixture was stirred vigorously for 24 h at room temperature. The generated precipitate was isolated by filtration and washed with diethyl ether (10 mL) and dichloromethane (10 mL). The crude product was purified by recrystallisation from methanol.

General procedure for the synthesis of $[\text{Cu}(\text{terpy-X})_2][\text{NO}_3]_2$:

A solution of the terpy-X ligand (70-83 mg, 0.30 mmol) was dissolved in dry methanol/dichloromethane (1:1, 20 mL) under N_2 atmosphere. A solution of $\text{Cu}(\text{NO}_3)_2 \cdot x\text{H}_2\text{O}$ (56 mg, 0.15 mmol) was dissolved in 20 mL of dry methanol was added dropwise. The mixture was stirred vigorously for 24 h at room temperature. The generated precipitate was isolated by filtration and washed with diethyl ether (10 mL) and dichloromethane (10 mL). The crude product was purified by recrystallisation from methanol.

2.4. Single crystal X-ray diffraction

All single crystal X-ray diffraction analyses were performed on Rigaku Oxford Diffraction instruments: the XtaLAB Synergy diffractometer (Pilatus 200 K detector) for **3** and **5**, and the SuperNova diffractometer (Atlas CCD detector) for **6**, **7** and **11**. Both instruments are dual microfocus X-ray diffractometers (two possible wavelengths Mo and Cu) equipped with Oxford liquid-nitrogen cryostream coolers. The selected single crystals were mounted using polybutene oil on a flexible loop fixed on a goniometer head and transferred to the diffractometer. Pre-experiments, data collections, data reductions and analytical absorption corrections[42] were performed with the program suite *CrysAlisPro*. [43] Using *Olex2*, [44] the structures were solved with the SHELXT[45] small molecule structure solution program and refined with the *SHELXL2018/3* program package[46] by full-matrix least-squares minimization on F^2 . All non-hydrogen atoms were refined anisotropically and hydrogen atoms were placed in calculated positions and refined as riding with C–H = 0.95 Å, $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ (for aromatic), C–H = 0.98 Å, $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C})$ (for methyl) and O–H = 0.85 Å, $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{O})$ (for water). The crystal data collections and structure refinement parameters are shown in Tables S1 – S3 . CCDC 2034245 (for **3**), 2034246 (for **5**), 2034247 (for **6**), 2034248 (for **7**), and 2034249 (for **11**) contain the supplementary crystallographic data for these compounds, and can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

2.5. Cell culture

All the cells lines were obtained from the animal experimental Centre of Sun Yat-Sen University (Guangzhou, China). The cell lines human adenocarcinomic alveolar basal epithelial (A549), cisplatin resistant human adenocarcinomic alveolar basal epithelial (A549R) and human liver (LO2) were maintained in DMEM media supplemented with fetal bovine serum (10%), penicillin (100 units/mL), streptomycin (50 units/mL) at 37 °C in a humidified atmosphere with 5% CO₂. The cisplatin resistance of A549R was maintained by cisplatin treatment (1 μM) for one week every month. Before an experiment, the cells were passaged three times.

2.6. Cytotoxicity assay

The cytotoxicity of a sample was accessed using a 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. Cells were seeded in 96 well plates and allowed to adhere upon incubation for 24 h. The cells were treated with increasing concentrations of the

compounds diluted in cell media achieving a total volume of 200 μL . All cells were incubated in the dark for 44 h. After this time, the media was replaced with fresh media containing MTT (20 μL , 5mg/ mL). After 4 h incubation, the absorption at 595 nm in each well was determined with a SpectraMax CMax Plus (Molecular Devices) absorbance microplate reader. The viability of the cells in each well was obtained by subtracting the average absorbance of the blank group.

3. RESULTS AND DISCUSSION

3.1. Synthesis

The terminally functionalised 2,2':6',2''-terpyridine ligands were prepared according to previously published synthetic procedures (Scheme S1).[37-41, 47] The synthesis of the complexes **1**[48-50], **2**[51], **7**[52-55], **8**[56], **10**[57] and **11**[58] has been previously reported while, to the best of our knowledge, the synthesis of **3-6**, **9** and **12** is reported here for the first time. The mono-coordinated dichloro complexes **1-6** were synthesised with one equivalent of the ligand and CuCl_2 whereas the bis-coordinated complexes **7-12** were prepared with two equivalents of the ligand and $\text{Cu}(\text{NO}_3)_2 \cdot x\text{H}_2\text{O}$ at room temperature. The compounds were isolated by recrystallisation from methanol and characterised using HR-MS spectrometry and IR spectroscopy (Figure S1-S12). The purity of the complexes was confirmed by elemental analysis. Worthy of note, previous studies on Cu(II) 2,2':6',2''-terpyridine complexes have suggested the high stability of such compounds in a biological environment.[31-33]

Figure 1. Chemical structures of the terminally-functionalised complexes of the type $[\text{Cu}(2,2':6',2''\text{-terpyridine})(\text{Cl})_2]$ **1-6** and $[\text{Cu}(2,2':6',2''\text{-terpyridine})_2][\text{NO}_3]_2$ **7-12**. The bis-coordinated complexes were isolated as nitrate salts.

3.2. X-ray crystallography

Perspective views of the molecular structures of **3**, **5**, **6**, **7** and **11** are shown in Figure 2. In the crystal structures of **5** and **6**, the asymmetric units contain two crystallographically independent Cu(II) molecules and isolated molecule(s) of water (one for **5**, and two for **6**). In the crystal structure of **7**, the Cu(II) molecule lies on several special positions, a two fold axis and a rotoinversion four-fold axis. Only one fourth of the molecule had to be refined, the other positions were obtained by symmetry operations. The nitrate anions and water molecules are severely disordered around symmetry elements. Restraints had to be used to correct the geometry of the counterions and the thermal parameters of the corresponding atoms. In the crystal structure of **11**, the asymmetric unit contains one Cu(II) molecule for two nitrate counterions and two isolated water molecules.

As revealed by the X-ray diffraction studies, the copper (II) atom in the terminally functionalised complexes of the type Cu(2,2':6',2''-terpyridine)(Cl)₂ **3** (Br), **5** (OMe) and **6** (NMe₂) is pentacoordinated in a distorted square-pyramidal geometry by one terpyridyl ligand atoms and two chlorido ligands. The terpyridyl ligand is coordinated in an usual manner acting as a tridentate N³ chelating ligand while one chlorine atom is in an apical position and the second one is in the so-called "basal plane" formed by the latter and the three nitrogen atoms. As expected, these four atoms are nearly coplanar in our crystal structures as confirmed by the calculated r.m.s. deviations (Table 1) of 0.1110 (**3**), 0.0795 and 0.0937 (**5**), and 0.0602 and 0.0655 (**6**). The metal center and the apical Cl ion are located on the same side of the basal plane, the former deviates from the basal plane by about 0.2 – 0.3 Å while the latter is at about 2.8 Å (the exact values are reported in Table 1). Concerning the bond distances and angles, the Cu–N bond of the central pyridine is shorter by about 0.1 Å than those of the external rings, and the Cu–Cl basal bond length is much shorter than the Cu–Cl apical bond length by more than 0.2 Å (Table 1). Such a difference between the Cu–Cl distances is attributed to the well-known Jahn Teller effect. In the crystal structures of the complexes of the type [Cu(2,2':6',2''-terpyridine)₂][NO₃]₂ **7** (H) and **11** (OMe) the metal center is hexacoordinated and exhibits a distorted octahedral coordination geometry. The two N³ coordinated terpyridyl ligands are nearly planar and perpendicular to each other in **7** (due to the Cu atom located on special positions) or nearly perpendicular in **11** since the dihedral angle between the mean plane is 87.24(3)°. Like in the dichloro complexes, the Cu–N bond distance of the central pyridine is significantly smaller than those of the external rings (by 0.15 – 0.25 Å, Table 2). Despite the

large number of aromatic rings in all our complexes, there are no strong $\pi\cdots\pi$ interactions in the crystal structures. These interactions correspond to slipped face-to-face π stacking with the shortest centroid – centroid distances of 3.573 (**3**), 3.493 (**5**), 3.594 (**6**), 3.634 (**7**) and 4.106 Å (**11**) and slipped distances in the range 0.925 – 1.175 Å (Tables 1 and 2).

Figure 2. The molecular structure of **3**, **5**, **6**, **7** and **11**. Solvent molecules and hydrogen atoms are excluded for clarity. For **5** and **6**, only one of the two crystallographically independent Cu(II) molecules is presented.

3.3. Biological Evaluation

The mono-coordinated dichloro complexes **1-6** were found to be poorly soluble in water and showed limited solubility even upon the addition of DMSO. For this reason, their cytotoxicity was not investigated. On the contrary, the bis-coordinated complexes **7-12** were highly water soluble. For this reason, the cytotoxicity of only **7-12** towards cancerous human adenocarcinomic alveolar basal epithelial (A549), the corresponding cisplatin resistant version

(A549R) and non-cancerous human liver (LO2) cells was investigated using a 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay (Table 3). Previous studies have shown that the toxicity of Cu(II) 2,2':6',2''-terpyridine complexes within a cellular model is highly increased upon incubation for several days.[33] Therefore, the complexes were incubated for 44 h and, after this time, the cell viability assessed. The complexes **7-9**, **11-12** were found to be cytotoxic in the nanomolar range ($IC_{50} = 150-1030$ nM) in A549 cells. As an exception, the carboxylic acid functionalized compound **10** was significantly less toxic ($IC_{50} = 38.92 \pm 4.50$ μ M). As the Cu complexes showed a similar cytotoxic effect in the non-cancerous cell line LO2, no selectivity for cancerous cells was observed. Promisingly, all complexes showed a comparable effect in the cisplatin resistant cell line A549R, indicating that these compounds could potentially be useful to overcome drug resistance. As the lead structure of this study, complex **7** was identified with a cytotoxicity in the nanomolar range ($IC_{50} = 80-180$ nM). These results are very encouraging as this compound is 82-times more cytotoxic in A549 cells and 242-times more cytotoxic in its drug resistant version A549R than the clinically approved drug cisplatin. Recent studies have demonstrated that structurally related Cu(II) 2,2':6',2''-terpyridine complexes trigger cell death by necrosis or apoptosis.[33]

Table 3. IC_{50} values (μ M) of the bis-coordinated Cu(II) complexes **7-12** against cancerous human adenocarcinomic alveolar basal epithelial (A549), cisplatin resistant human adenocarcinomic alveolar basal epithelial (A549R) and non-cancerous human liver (LO2) cells.

Compound	A549	A549R	LO2
7	0.15 \pm 0.01	0.18 \pm 0.07	0.08 \pm 0.01
8	0.59 \pm 0.05	0.64 \pm 0.04	0.23 \pm 0.02
9	1.03 \pm 0.07	0.93 \pm 0.11	0.52 \pm 0.06
10	38.92 \pm 4.50	40.02 \pm 3.56	21.35 \pm 0.95
11	0.73 \pm 0.03	0.60 \pm 0.08	0.37 \pm 0.01
12	0.87 \pm 0.09	0.95 \pm 0.16	0.35 \pm 0.04
cisplatin	12.35 \pm 1.23	43.5 \pm 3.93	16.75 \pm 2.33

4. CONCLUSIONS

In this study, we report on the synthesis, characterisation and biological evaluation of Cu(II) 2,2':6',2''-terpyridine complexes as potential anticancer agents. Terminally functionalised metal complexes of the type $[\text{Cu}(2,2':6',2''\text{-terpyridine})(\text{Cl})_2]$ and $[\text{Cu}(2,2':6',2''\text{-terpyridine})_2][\text{NO}_3]_2$ were synthesised and characterized by HR-MS and IR spectroscopy. Several compounds were further characterised by single crystal X-ray diffraction studies. Due to poor water solubility of the mono-coordinated complexes, only the bis-coordinated complexes were investigated in a human adenocarcinomic alveolar basal epithelial cell model. The complexes, except for the carboxylic acid functionalised derivative, were found to have a cytotoxicity in the nanomolar range, an order of magnitude more toxic than the clinically applied anticancer agent cisplatin. Promisingly, the compounds had an equal effect in the corresponding cisplatin resistant cancer cell line, making them potentially useful for applications to overcome drug resistant cancers.

HIGHLIGHTS

- Synthesis of terminally functionalised Cu(II) polypyridine of the type [Cu(2,2':6',2''-terpyridine)(Cl)₂] and [Cu(2,2':6',2''-terpyridine)₂][NO₃]₂.
- Single crystal X-ray analysis of metal complexes.
- Biological evaluation revealed cytotoxicity of lead compounds in the nanomolar range against human adenocarcinomic alveolar basal epithelial cells.
- Effective in drug resistant cancer cell line.
