Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

Pd-catalyzed Debenzylation and Deallylation of Ethers and Esters with Sodium Hydride

ABSTRACT: Herein we demonstrate simply the addition of Pd(OAc)₂ as a promotor switches the reactivity of a commonly used base NaH to a nucleophilic reductant. The reactivity is engineered into a palladium-catalyzed reductive debenzylation and deallylation of aryl ethers and esters. This operationally simple, mild protocol displays a broad substrate scope and a broad spectrum of functional group tolerance (>50 examples) and high chemoselectivity towards aryl ethers over aliphatic structures. Moreover, the dual reactivity of NaH as a base and a reductant is demonstrated in efficient synthetic elaboration.

KEYWORDS: sodium hydride, palladium, reduction, debenzylation, deallylation.

Cheap and structurally simple NaH is one of the most widely used reagents in chemical research. It is generally used as a base in organic synthesis.¹ In sharp contrast, it is rarely used as a reductant or a nucleophile.^{2,3} In this context, recent elegant studies from the groups of Chiba⁴ and Studer⁵ reveal such highly sought utility in organic reactions. The Chiba and coworkers developed a series of unique NaH-LiI or NaI composite mediated organic transformations including the reduction of nitriles, amides, and imines,^{4a,b} dehalogenation of aryl halides,^{4c} amide-directed C-H sodiation,^{4d} and nucleophilic amination of methoxy arenes (Scheme 1a).^{4e} Studer et al reported an unprecedented radical hydrodehalogenation of aryl bromides and chlorides using NaH and 1,4-dioxane as reagents and 1,10-phenanthroline as a radical initiator (Scheme 1b). These studies underscore the enormous synthetic potential of cheap and readily stored and handled, but much less explored NaH as a reducing reagent or a nucleophile for organic transformation.

Herein, we report new findings that simply the employment of Pd(OAc)₂ as a promotor switches the reactivity of commonly used base NaH to a nucleophilic reductant (Scheme 1c). The new reactivity is transformed into a new palladium-catalyzed reductive debenzylation and deallylation of aryl ethers and esters. This operationally simple, mild protocol displays a broad substrate scope and a broad spectrum of functional group tolerance (>50 examples) and high chemoselectivity towards aryl ethers over aliphatic ones. Moreover, the dual reactivity of NaH as a base and a nucleophile is explored in efficient synthetic elaboration. It is noteworthy that benzyl and allyl functionalities are widely used as protecting groups for hydroxyl and carboxylate groups. General deprotection

methods employ Pd-catalyzed hydrogenolysis⁶ and Rh-promoted isomerization of double bonds⁷ for debenzylation and deallylation, respectively. However, our method unifies the two protocols enabling the removal of both protecting groups under the same reaction conditions.

Scheme 1. Reactions mediated by NaH as a reductant or a nucleophile

a) NaH/NaI or LiI mediated transformations reported by Chiba et al.

b) NaH and 1,4-dioxane with 1,10-phenanthroline mediated hydrodehalogenation reported by Studer

c) This work:

We commenced the studies by treating 1-(benzyloxy)naphthalene (**1a**) with NaH (1.5 equiv) and various catalysts (5 mol %) in THF (Table 1, entries 1-4 and supporting information) under an N₂ atmosphere. In the absence of catalyst, no conversion was observed after

applicable to the double debenzoylation of **3s** to give di-phenol **4s** in high yield.

Next, the chemoselectivity of the methodology was investigated when different benzyl groups appeared in one molecule (Scheme 2c). It was found that cleavage occurred exclusively on the aryl benzyl ether but not on the *N,N*-dibenzylbenzamide (**4t**) or the alkyl benzyl ether (**4u** and **4v**).¹² Furthermore, to demonstrate the orthogonal capacity, additional suitable protecting groups such as broadly used TBS and THP were subjected to the standard reaction conditions and gave the desired debenzoylation products **4w** and **4x** in good yields. Allyl groups are also easily removed by the established protocol. Some representative substrates **5** bearing common functional groups including OMe, Ac, NO₂, CN, and CHO underwent deallylation under even milder conditions (rt) in 4 h to give desired phenols **6** in good yields (Scheme 2d).

The conversion of esters to carboxylic acids is an meaningful deprotection reaction in synthesis. The deprotection of corresponding benzyl and allyl carboxylates occurs even more easily than the that of the corresponding aryl ethers. Representative benzyl and allyl ester substrates with various substituents were reacted smoothly with NaH/Pd(OAc)₂ in DMA and furnished carboxylic acids in good yields (Scheme 3).

Scheme 3. Scope of the deprotection of benzyl and allyl esters

We envisioned that taking advantage of the dual reactivity of NaH as a base and a reductant, the efficient synthesis of more complex structures, which otherwise take multistep process, is feasible. In the first attempt, we selected readily prepared **11** as the starting material for the one-pot synthesis. Treatment of **11** with EtBr and 1.2 equiv of NaH gave **12** as the only product, and subsequent addition of Pd(OAc)₂ and an additional 1.4 equiv of NaH led to the formation of sodium phenolate, which was directly reacted with (bromomethyl)cyclopropane **13** to provide the final product **14** in 74% overall yield for the one-pot three step synthesis (Scheme 4a). The second example is the well-known malonic ester synthesis (Scheme 4b). Dialkylation of malonate **15** using BnBr, followed by treatment with NaH/Pd(OAc)₂ in one-pot, gave decarboxylation product **17** in 92% yield. To the best of our knowledge, this represents the most efficient synthetic

operation to this kind of structure reported to date.¹³ The third case is the preparation of 2-benzylbenzoic acid **20** via a two-step pathway (Scheme 4c). The benzyl moiety of **19** was efficiently reduced to a methylene, which is different from the above mentioned reactions since the focus here is on the transformation of the benzyl group instead of the deprotection of a phenol or carboxylic acid. Similarly, this strategy can be employed for the introduction of alkyl fragment at benzyl or allyl position as indicated by the facile syntheses of **24** and **28** (Scheme 4d and Scheme S1, respectively). Key precursor **23** was generated from hemiacetal **21**¹⁴ in straightforward two-step synthesis. The final reduction steps were mild, and efficiently provided the alkylation products in good yields. The atom- and step-economy of the developed methods are clearly demonstrated in these syntheses, highlighting the unique power of NaH in organic synthesis.

Scheme 4. Exploration of NaH as reductant in efficient synthetic elaboration

Based on the general mechanism of a typical Pd-promoted debenzoylation reaction, a plausible catalytic cycle for the new transformation was proposed (Scheme 5). Pd(o) is initially formed by reduction of Pd(OAc)₂ with NaH.¹⁵ Aryl benzyl ether **29** undergoes oxidative addition followed by ion exchange of ArO⁻ and hydride anion between **30** and NaH, which provides ArONa and intermediate **31**. Finally, reductive elimination of **31** releases toluene and regenerates the Pd(o) catalyst.

Scheme 5. The proposed catalytic cycle

In conclusion, we have developed a new protocol for the deprotection of aryl benzyl/allyl ethers and benzyl/allyl esters using NaH as a nucleophile in high yield and with a broad substrate scope and a wide spectrum of functional group tolerance. The method exhibits high

chemoselectivity towards aryl ethers over aliphatic ones. These features render the new deprotection methodology potentially useful in the protection of -OH and COOH in organic synthesis. Furthermore, the key component of the process is the uncovering of Pd(OAc)₂ as a promoter, capable of switching the reactivity of NaH from base to a nucleophile. Further studies along this direction are currently underway in our laboratories and will be reported in due course.
