#### Abstract

$N$-\{4-[2-(2-Amino-4(3H)-oxo-5H-pyrrolo[3,2-d]pyrimidin-5-yl)ethyl]benzoyl\}-L-glutamic acid (3a) and $N$-\{4-[3-(2-amino-4(3H)-oxo-5H-pyrrolo[3,2-d]pyrimidin-5-yl)propyl]benzoyl\}-L-glutamic acid (3b) were synthesized as potential anticancer agents.

In the course of our program directed toward the design and synthesis of inhibitors of folate-dependent biochemical processes as antitumor agents, ${ }^{1}$ we recently synthesized $N$-\{4-[2-(2-amino-4(3H)-oxo-7H-pyrrolo[2,3-d]pyri-midin-5-yl)ethyl]benzoyl\}-L-glutamic acid (1, LY231514) ${ }^{2}$ as an analogue of DDATHF [(6RS)-2] $]^{1,3}$ in which C-5 of the latter was deleted and the B ring aromatized. This compound, which was found to be a potent inhibitor of tumor growth both in vitro and in vivo, primarily as a consequence of inhibition of thymidylate synthase, is currently in Phase II clinical trials.
Pyrrolo[3,2-d]pyrimidine 3a is a structural isomer of LY231514 (1) in which the pyrrole ring has been inverted. This modification leaves the distribution of the steric bulk and electronics of the molecule intact, but removes a potential hydrogen bond donor from position 7. By extending the alkyl chain which connects the pyrrole ring with the $N$-benzoylglutamate moiety by one methylene unit, target molecule 3b more closely approximates the length of the spacer chain in DDATHF (2). The synthesis and inhibitory activity against dihydrofolate reductase (DHFR) of the 2,4-diaminopyrrolo[3,2-d]pyrimidine derivatives $4 a$ and $\mathbf{4 b}$ have recently been reported. ${ }^{4}$
The key steps envisioned for the preparation of our target compounds 3a and 3b are illustrated in Scheme 1. It was anticipated that an appropriate derivative of pyrrolo[3,2-d]pyrimidine $5{ }^{5}$ could be substituted at N-5 using suitable alkylating reagents (i.e. the hydroxyethyl derivative 6a, the bromoethyl derivative 6b, or the iodopropyl derivative 6c) and the N -alkylated products then converted to the target analogues $\mathbf{3 a}$ and $\mathbf{3 b}$ by previously exploited deprotection and amino acid coupling steps. ${ }^{1,6-8}$

[^0]

A protected derivative of pyrrolopyrimidine $5^{5}$ was synthesized in four steps from the readily accessible 2-amino-6-methyl-5-nitro-4(3H)-pyrimidinone (8). ${ }^{9}$ Our synthetic plan involving formylation of the 6 -methyl group of 8 , followed by reductive ring closure, is a variant of the Batcho-Leimgruber indole synthesis. ${ }^{10,11}$ However, treatment of 8 with DMF dimethylacetal at $60^{\circ} \mathrm{C}$ unexpectedly gave the N -methylated derivative 9 in $92 \%$ yield (Scheme 2). The stereochemistry of the enamine side chain at position 6 was deduced as ( $E$ ) on the basis of the observed coupling constant of 12.3 Hz for the two olefinic protons. The extraneous methyl group was assigned to N-3 based upon (1) the presence of a carbonyl IR stretch at $1661 \mathrm{~cm}^{-1}$, indicating an intact lactam

functionality, and thus the absence of O-methylation, and (2) the assumption that methylation had probably occurred at the sterically less congested ring nitrogen atom. Nevertheless, the feasibility of the projected pyrrole annulation reaction was readily demonstrated by reduction of 9 with sodium hydrosulfite to give in $96 \%$ yield the pyrrolo[ $3,2-d]$ pyrimidine 10 , which was then deprotected with 1 N NaOH to yield 1-methyl-9-deazaguanine (11).

Treatment of 8 with DMF dimethylacetal in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature for 1 h generated compound 12 ( $91 \%$, Scheme 3). Reaction of pyrimidine 12 with 1.1 equiv of sodium hydride followed by addition of excess chloromethyl pivalate produced a $4: 1$ mixture of $13(60 \%)$ and its O-alkylated isomer 14 ( $15 \%$ ), separated by column chromatography. The protected pyrimidine 13 was then converted to 15 in $86 \%$ yield with DMF dimethylacetal at room temperature. ${ }^{12}$ Subsequent reduction of the nitro group of 15 led directly to 16 ( $94 \%$ yield), which was deprotected with 1 N NaOH to form 9-deazaguanine

(5). ${ }^{13,14}$ To the best of our knowledge there are only two previous syntheses of 9 -deazaguanine (5). The method of Imai ${ }^{13}$ is long and low-yielding ( 10 steps, $<1 \%$ yield) while the method of Klein ${ }^{14}$ failed in our hands. Furthermore, our synthesis produces the fully protected and soluble 2 -amino-4(3H)-oxo-5H-pyrrolo[3,2-d]pyrimidine derivative 16 suitable for further transformations.

It was hoped that Mitsunobu coupling ${ }^{15}$ of 16 with the hydroxyethyl derivative $6 a^{16}$ would lead to pyrrolopyrimidine 17. Disappointingly, however, Mitsunobu coupling of alcohol $6 \mathbf{a}$ with the protected pyrrolopyrimidine 16 produced a mixture of the desired product 17 contaminated with a range of side products, and attempts to purify the material were fruitless. We thus turned to attempts to alkylate 16 with the primary bromide 6 b , which was prepared by esterification of 4 -carboxyphenethyl bromide ${ }^{17}$ with isobutylene/sulfuric acid. Addition of 1.1 equiv of NaH in DMF to pyrrolo[3,2-d]pyrimidine 16, followed by bromide 6 b , gave the desired alkylation product 17 in only $10 \%$ yield, in addition to considerable recovered starting material 16 ( $83 \%$ ) and a small amount ( $8 \%$ ) of tert-butyl 4 -vinylbenzoate ${ }^{16,18,19}(8 \%)$ (Scheme 4).

Reagents: a: TFA, $\mathrm{CH}_{2} \mathrm{Cl}_{2} ; \mathrm{b}$ : N -methyimorpholine, 2-chloro-4,6-dimethoxy-1,3,5-triazine, dimethyl L-givtamate hydrochloride; c: 1 N NaOH .

Despite the fact that all efforts to find conditions which would promote displacement over elimination (variations in solvent, use of crown ethers, different counter-anions, etc.) were unsuccessful, the yield of $\mathbf{1 7}$ based upon recovered starting material averaged $61 \%$. Since the starting bromide 6b was readily available, we decided to focus our attention on the final stages of our projected syntheses.
Scheme 5 illustrates the remaining reactions utilized to generate the target molecule 3a. The tert-butyl ester 17 was converted to the free acid 18 with trifluoroacetic acid in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $98 \%$ yield). Coupling of 18 with dimethyl L-glutamate using $N$-methylmorpholine and 2-chloro-4,6-dimethoxy-1,3,5-triazine ${ }^{20}$ gave 19 in $63 \%$ yield. The final target antifolate 3 a was then obtained ( $69 \%$ yield) in the usual way by saponification with 1 N NaOH .
The synthesis of target molecule $\mathbf{3 b}$ proved to be straightforward. The alkyl iodide $\mathbf{6 c}$ was synthesized by a series of reactions (Scheme 6) previously utilized ${ }^{21}$ to generate the corresponding methyl ester of $\mathbf{6 c} .^{22}$ Thus,

commercially available 4-iodobenzoic acid (20) was esterified with sulfuric acid in isobutylene/methylene chloride to generate 21 ( $87 \%$ ). A palladium-catalyzed coupling of 21 with propargyl alcohol gave the alkyne 22 in $62 \%$ yield. Reduction to the primary alcohol 23 ( $93 \%$ ), conversion to the mesylate $24(97 \%)$, and subsequent reaction with NaI in acetone then produced iodide $\mathbf{6 c}$ (95\%).

Addition of sodium hydride to pyrrolopyrimidine 16, followed by iodide $\mathbf{6 c}$, gave 25 in $78 \%$ yield (Scheme 7 ), The free acid 26, obtained in $95 \%$ yield from 25 with trifluoroacetic acid in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, was coupled with dimethyl L-glutamate hydrochloride as described above ( $75 \%$ yield), and final saponification then gave the target antifolate 3b ( $62 \%$ yield).

The two target analogs $\mathbf{3 a}$ and $\mathbf{3 b}$ were tested for in vitro inhibition of human CCRF-CEM lymphoblastic leukemic cell growth and found to have $\mathrm{IC}_{50}$ values of $0.2 \mu \mathrm{~g} / \mathrm{mL}$ and $0.4 \mu \mathrm{~g} / \mathrm{mL}$, respectively, some two orders of magnitude less than those of the lead compounds 1 $(0.007 \mu \mathrm{~g} / \mathrm{mL})$ and $2(0.007 \mu \mathrm{~g} / \mathrm{mL})$. These results suggest

that the hydrogen-bonding donor $\mathrm{N}-\mathrm{H}$ at position 7 in LY231514 (1) may be critically important for maximum cell growth inhibitory activity. ${ }^{23}$
