# 45. Synthesis of 3-Adenyl- and 3-Thyminylcyclobutane-1,1-dimethanols and Their Homo-octameric Phosphodiesters 

by Jean-Michel Henlin, Hans Rink, Erich Spieser, and Gerhard Baschang*<br>Research Department, Pharmaceuticals Division, Ciba-Geigy Lid., CH-4002 Basel

(31.X.91)

#### Abstract

Starting from 3-(benzyloxy)cyclobutane-1,1-dimethanol, 3-thyminyl- and 3-adenylcyclobutane-1,1-dimethanol were synthesized by direct introduction of the heterocycles (Scheme 1). The mono-O-substituted methoxytrityl derivatives were separately converted to octameric phosphodiesters on an aminomethyl-polystyrene carrier by the phosphotriester method. These oligomers of carba-nucleosides were prepared in order to study their annealing behaviour towards ribo- and deoxyribo-nucleic acids as well as their potential for homologous hybridization.

Introduction. - Since the discovery of oxetanocin [1] (I), nucleoside analogues with a four-membered ring replacing deoxyribose became objects of intense research. Apart from the synthesis of I itself [2] [3], several publications of cyclobutane analogues appeared with the aim to find new compounds with antibiotic and especially antiviral activity [4-7]. In contrast, we wished to explore the additional potential of such compounds as building blocks of oligonucleotides in order to test their annealing behaviour towards deoxy- and ribonucleic acids. We were attracted by the symmetry of 3-(hetero-cyclyl)cyclobutane-1,1-dimethanols') II. Homo-oligonucleotides made from such monomers should not give rise to $\alpha$ - and $\beta$-configurated isomers, e.g., which may differ drastically in their annealing behaviour toward RNA. In this communication, we describe the synthesis of 3-adenyl- and 3-thyminylcyclobutane-1,1-dimethanol which differs from that which was recently reported [8] [9].

I Ade = Adenin-9-yl, Oxetanocin

II $\mathrm{R}=\mathrm{OH}, \mathrm{X}=$ base

Results. - Starting from the known 3-(benzyloxy)cyclobutane-1,1-dimethanol [10] [11], we prepared diester $\mathbf{1}$ and then, via 2 and $\mathbf{3}$, the 6,8-dioxaspiro[3.5]nonan-2-ol (4; Scheme 1). Various sulfonate esters of 4 were examined for the introduction of the thymine or adenine moiety. In the series methanesulfonate, benzenesulfonate, 4-bromo-

[^0]Schemel

a) $\mathrm{LiAlH}_{4}$, DME, $48 \mathrm{~h}, 90^{\circ}(85 \%)$. b) TsOH (cat), 2,2-dimethoxypropane ( $96-98 \%$ ). c) $\mathrm{H}_{2}$, $\mathrm{Pd} / \mathrm{C}, \mathrm{AcOEt}$, r.t. $(90-97 \%)$. d) $\mathrm{BrsCl}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 16 \mathrm{~h}$, r.t. ( $44 \%$ ). e) Adenine ( 3 equiv.), DBU ( 3 equiv.), DMSO, $24 \mathrm{~h}, 80^{\circ}$ ( $90 \%$ ). f) Thymine ( 3 equiv.), DBU ( 3 equiv.), DMSO, $24 \mathrm{~h}, 80^{\circ} ; 7:\left(55 \%\right.$ ); 8: ( $34.2 \%$ ). g) 1. Chromatography ( $\mathbf{9}, \mathbf{1 0}: 70 \% ; \mathbf{1 1 : 7 8 \%}$ ).
benzenesulfonate, and 4-nitrobenzenesulfonate, the best properties with respect to stability and reaction conditions for substitution were observed with the 4 -bromobenzenesulfonate ( BrsO ) 5. Introduction of adenine was accomplished in $90 \%$ yield in DMSO at $80^{\circ}$ for 24 h: we detected $N^{9}$-substituted product 6 only (TLC). Substitution using 3 equiv. of thymine under the same conditions led to a mixture of 3 products: $N^{\mathrm{L}}$-substituted 7 ( $75 \%$ ), the disubstituted $8(34 \%)$, and traces of $N^{3}$-substituted product. Even a 4 -fold excess of thymine did not suppress the formation of 8 . The desired compounds 6 and 7 could be purified by flash chromatography and were deprotected with HCl in dioxane to give the dimethanols 9 and 11. Deprotection of $\mathbf{8}$ yielded $\mathbf{1 0}$.

Reaction of 11 with 1.3 equiv. of monomethoxytrityl chloride $(\mathrm{MeOTrCl})$ in pyridine led to two mono- $O$-substituted products 12 ( $35 \%$ ) and $13(42 \%)$ as well as to the di- $O$-substituted derivative ( $9 \%$ ) together with unreacted $\mathbf{1 1}(6.5 \%$ ). Addition of more MeOTrCl did not diminish the amount of diol 11 appreaciably, but rather increased the amount of di- $O$-substituted product (Scheme 2). Compounds 12 and 13 were each processed by the phosphotriester method [12] to octameric phosphodiesters on a solid support with thymidine as a starting nucleoside. Because of the asymmetry of the resulting oligonucleotides, 12 led to a pseudo- $\beta$ - (see 14), whereas 13 led to a pseudo- $\alpha$ oligomer (see 15). We purposely used these commercially available resins because we hoped to get further information on the degree of disorder introduced by the natural

nucleosides by measuring the melting behaviour of the pseudo- $\alpha$ - and pseudo- $\beta$ oligomers in the presence of complementary RNA's and DNA's.

In the adenine series, we first protected the base moiety of 6 by benzoylation giving the $N^{6}, N^{6}$-dibenzoate 16 in $95 \%$ yield (Scheme 3). Further conversion to the desired $N^{6}$-ben-zoyl- $O$-methoxytrityl derivatives $\mathbf{2 2}$ and $\mathbf{2 3}$ was achieved in two different ways. Removal of the isopropylidene group of $\mathbf{1 6}(\rightarrow \mathbf{1 8})$ and monomethoxytritylation $(\rightarrow \mathbf{1 9 / 2 0})$ prior to mono-debenzoylation with ammonia in THF proved to be more efficient, giving the

24
a) Solid-phase synthesis: $80-87 \%$ per coupling step.
desired 22 and $\mathbf{2 3}$ each in $11 \%$ overall yield. The route via $\mathbf{1 7}$ and $\mathbf{2 1}$ gave $\mathbf{2 3}$ in $10 \%$ and 22 in $3.5 \%$ overall yield. Alcohols 22 and 23 were again separately processed to octameric phosphodiesters on a solid support with $2^{\prime}$-deoxyadenosine as a starting nucleoside, 23 giving a pseudo- $\beta$ - (see 25) and $\mathbf{2 2}$ giving a pseudo- $\alpha$-oligomer (see 24; Scheme 4).

The structure of $\mathbf{1 2}$ and $\mathbf{1 3}$ was deduced from NOE experiments. With $\mathbf{1 2}$, irradiation at the $\left.\mathrm{H}_{z}-\mathrm{C}(3)^{\prime}\right)$ signal gave a positive effect on the $\mathrm{CH}_{2}$ protons of $\mathrm{CH}_{2} \mathrm{OH}$ as well as on $\mathrm{H}_{\alpha}-\mathrm{C}(2)$ and $\mathrm{H}_{\alpha}-\mathrm{C}(4)$, whereas in 13 this effect was seen on $\mathrm{CH}_{2} \mathrm{OTrOMe}, \mathrm{H}_{\alpha}-\mathrm{C}(2)$, and $\left.\mathrm{H}_{\alpha}-\mathrm{C}(4)^{1}\right)$. The substitution pattern of $\mathbf{2 2}$ and $\mathbf{2 3}$ was revealed similarly by irradiation at the $\mathrm{H}_{x}-\mathrm{C}(3)^{\mathrm{i}}$ ) signal giving NOE's on protons cis to $\mathrm{H}_{\alpha}-\mathrm{C}(3)$.

All oligomers were characterized by mass spectrometry and by their mobility relative to xylenecyanol and bromophenol blue in polyacrylamide gel electrophoresis (PAGE). Specifically, 14 and 15 were measured by laser-ionisation desorption MS and run on $12 \%$ PAGE, whereas for 24 and 25 we used electrospray-ionisation MS and 20\% PAGE (Table).

Table. Molecular Masses M and Electrophoresis Mobilities of Oligonucleotides 14, 15, 24, and 25

|  | Rel. mobility on PAGE ( $12 \%$ ) | $M$ by laser MS |  |  | Rel. mobility on PAGE (20\%) | $M$ by electrospray MS |  |

| 15 | 0.90 | 2356.9 | 2357.8 |  |  |  |  |

Furthermore, we also prepared the adenyl-cyclobutanemethanols cis- and trans- 36 (Scheme 5). In our hands, the best route to the desired intermediates cis- and trans- $\mathbf{3 0}$ was via 26-29 and chromatographic separation of the ethyl carboxylates cis- and trans-29. The following procedure was applied separately to both cis- and trans-29. Reduction of the COOEt group with $\mathrm{LiAlH}_{4}(\rightarrow \mathbf{3 0})$, protection with (tert-butyl)diphenylsilyl chloride $(\rightarrow \mathbf{3 1})$, hydrogenolytic removal of the benzyl group ( $\rightarrow \mathbf{3 2}$ ), introduction of the leaving group with 4-bromobenzenesulfonyl chloride ( $\rightarrow 33$ ), and substitution with adenine in the presence of DBU in DMSO led to the silyl-protected $N^{9}$-substituted derivatives 34

a) $\mathrm{KOH}, \mathrm{EtOH} / \mathrm{H}_{2} \mathrm{O}$, reflux for 5 h . b) $\mathrm{CO}_{2}, 180^{\circ} / 0.02 \mathrm{Torr}\left(80 \%\right.$ for 2 steps). c) $\mathrm{ClCOCOCl}, \mathrm{CCl}_{4}$. d) EtOH , $\mathrm{CCl}_{4}$. e) Chromatography. $f$ ) $\mathrm{LiAlH}_{4}\left(0.75\right.$ equiv.), DME, 15 h, r.t. $(80 \%)$. $g$ ) $(t-\mathrm{Bu}) \mathrm{Ph}_{2} \mathrm{SiCl}$, imidazole, DMF. h) $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}, \mathrm{DME}\left(72 \%\right.$ for 2 steps). i) $\mathrm{BrsCl}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}(95 \%)$.j) Adenine, DBU, DMSO, $35 \mathrm{~h}, 80^{\circ}(46 \%)$. k) $\mathrm{HF} /$ urea, THF
together with the corresponding $N^{7}$-substituted derivatives 35 . In both the cis- and the trans-series, $\mathbf{3 4}$ and 35 were separated by chromatography. Final deprotection of 34 with HF in urea gave 36.

For the introduction of $N^{4}$-isobutyryl-cytosine and 2-amino-6-(methoxyethoxy)purine into 32, the benzenesulfonate rather than $\mathbf{3 3}$ proved to be the more efficient (unpublished).

Discussion. - While some oxetane- and cyclobutane-derived nucleosides obviously behave as antimetabolites in antiviral tests, it is not clear if oligomeric phosphodiesters of such nucleoside derivatives are able to function as surrogates of oligonucleotides and would hybridize, e.g., with RNA or DNA. Moreover, we wished to know if pairing between homologous complementary species were possible. With no reliable prognosis of computer-assisted molecular modelling at hand, we relied on inspection of Dreiding models, observing the well accepted stereochemical and stereoelectronic (phospho diesters) rules. However, the final answer had to come from synthesis and physicochemical tests ${ }^{2}$ ).

The recently reported syntheses of 3-adenylcyclobutane-1,1-dimethanol both make use of the 3 -amino derivative which is elaborated to the end products by stepwise synthesis of the heterocyclic-base moiety [8] [9]. In contrast, we introduced the base moiety directly by exploiting the preferential alkylation of adenine at $N^{9}$ and of thymine at $N^{\mathrm{L}}$. The isomeric $N^{3}$-substituted thymine was expected to be formed; however, the relatively high proportion of $N^{1}, N^{3}$-disubstituted derivative $\mathbf{8}$ was unexpected.

[^1]After proper protection of the adenine group, elaboration of the monomeric cyclobutanedimethanols to oligomeric phosphodiesters followed the well established phosphotriester method. In particular, the methoxytrityl-carbanucleosides were phosphorylated according to the method described by van Boom et al. [12]. The resulting carbanucleotide benzotriazolyl esters were assembled to oligomers by a solid-phase process in a semiautomated continuous-flow synthesizer. While the oligomers containing thymine were formed in good yield ( $95-98 \%$ per coupling step) and could be purified by simple gel chromatography, the coupling procedure was less suitable for the adenine derivatives. Coupling yields were low ( $75-90 \%$ per step) for unknown reasons, and the mixture of oligomers had to be fractionated by ion-exchange chromatography on Mono Q HR 5/5 (Pharmacia). In view of this, the phosphoramidite method may be a viable alternative.

With the octamers in hand, the pairing behaviour toward various ribonucleic and deoxyribonucleic acids was studied. The corresponding results are to be reported elsewhere.

We thank Prof. H. Fritz, Drs. H. Fuhrer, and E. Keller for NMR measurements, Dr. D. Mueller for mass-spectrometric determinations, Mr. M. Faupel for capillary electrophoresis, and Mr. F. Ossola for skilled assistance in some experiments.

## Experimental Part

General. Flash chromatography (FC): silica gel Merck 60, 230-400 Mesh ASTM; alumina B, act. I (ICN Biomedicals No. 02072), Hyflo (Fluka No. 56678), molecular sieves ( 0.4 and 0.3 nm , beads ca. 2 mm ; Merck No. 5704 and 5708 ). TLC: Merck silica gel $60 F_{254}$ precoated, layer thickness $0.25 \mathrm{~mm} . \mathrm{CH}_{2} \mathrm{Cl}_{2}$ was stored over $0.4-\mathrm{nm}$ molecular sieves, 1,2 -dimethoxyethane (DME) passed over basic alumina before use, dimethylsulfoxide (DMSO) distilled under vacuum and stored over $0.4-\mathrm{nm}$ molecular sieves, dioxane passed over basic alumina before use, EtOH stored over $0.3-\mathrm{nm}$ molecular sieves, pyridine distilled and stored over $0.4-\mathrm{nm}$ molecular sieves, tetrahydrofuran (THF) distilled over potassionaphthalene and stored over $0.4-\mathrm{nm}$ molecular sieves, toluene distilled and stored over $0.4-\mathrm{nm}$ molecular sieves, and $\mathrm{Et}_{3} \mathrm{~N}$ distilled and stored over $0.4-\mathrm{nm}$ molecular sieves. Solvents for chromatography (ratios in $v / v$ ) were distilled before use. Melting point: Büchi apparatus by Dr. Tottoli. UV spectra: Perkin-Elmer-Lambda-9 UV/VIS/NIR spectrometer; $\lambda_{\max }$ in nm ( $\varepsilon$ ). IR spectra: Perkin-Elmer model 881 ; film, 1 drop of substance between 2 NaCl plates. NMR spectra: 200 MHz , Varian GEM $200 ; 300 \mathrm{MHz}$, Varian GEM $300 ; 400 \mathrm{MHz}$, Bruker WM $400 ; \delta$ in ppm, $J$ in Hz ; solvent internal reference $\mathrm{CDCl}_{3},{ }^{1} \mathrm{H} 7.265 \mathrm{ppm},{ }^{13} \mathrm{C}$ $77.00 \mathrm{ppm} ; \mathrm{CD}_{3} \mathrm{OD},{ }^{1} \mathrm{H} 3.34 \mathrm{ppm},{ }^{13} \mathrm{C} 49.00 \mathrm{ppm} ;$ DMSO, ${ }^{1} \mathrm{H} 2.50 \mathrm{ppm},{ }^{13} \mathrm{C} 39.70 \mathrm{ppm} ;{ }^{13} \mathrm{C}$, completely decoupled and APT spectra, off-resonance decoupled spectra only if necessary. Mass spectra: $2 A B, H F$ apparatus, FAB technique, thioglycerol as solvent.

Diethyl 3-(Benzyloxy)cyclobutane-I, I-dicarboxylate (1) was prepared according to [10] [11] with some improvements: Diethyl malonate ( $258.6 \mathrm{ml}, 1.703 \mathrm{~mol}$ ) was added neat within 2 h to a suspension of $\mathrm{NaH}(51.10 \mathrm{~g}$, 1.703 mol ; Fluka No. $71614,80 \% \mathrm{NaH}$ in oil) in dioxane ( 1000 ml ). This soln. was stirred 90 min at r.t. Then 2-(benzyloxy)-1-bromo-3-chloropropane ( $500 \mathrm{~g}, 1.789 \mathrm{~mol}$ ) was added neat within 1 h . The mixture was stirred for 1 h at r.t., followed by 24 h at $125^{\circ}$. After slow cooling to r.t., the same quantity of NaH was added neat in $5-\mathrm{g}$ portions within 1 h . The suspension was then slowly heated to $125^{\circ}$, mechanically stirred for 120 h at this temp. and worked up as described. The product was first purified by distillation at $172^{\circ} \% .6$ Torr, followed by FC ( $\left.t-\mathrm{Bu}\right)$ OMe/hexane $1: 99$ to $2: 8): 382.5 \mathrm{~g}(73.3 \%)$ of $\mathbf{1}$. Colourless oil.
$3 \beta$-(Benzyloxy) cyclobutane-1,1-dimethanol (2). A soln. of $\mathbf{1}(95.8 \mathrm{~g}, 313 \mathrm{mmol})$ in DME ( 80 ml ) was added dropwise at r.t. under Ar to a suspension of $\mathrm{LiAlH}_{4}(15 \mathrm{~g}, 395 \mathrm{mmol})$ in DME $(360 \mathrm{ml})$, so as to maintain the temp. $<50^{\circ}\left(\mathrm{TLC}\right.$ control ( AcOEt ): $R_{\mathrm{f}} 0.30$ ). The mixture was stirred under Ar at r.t. for 48 h . After completion of the reaction, $\mathrm{H}_{2} \mathrm{O}(10 \mathrm{ml})$ was slowly added with vigorous stirring. The mixture was then transferred into a 2-1 flask containing silica gel ( 800 ml ) and the solvent removed under vacuum until a fine powder was obtained. This powder was added to a $5-\mathrm{cm}$ Hyflo pad on a fritteglass and washed with AcOEt ( 400 ml fractions, TLC control). The fractions containing product were evaporated to give $55 \mathrm{~g}(79 \%)$ of crude crystalline 2. Recrystallization from $\mathrm{AcOEt} / \mathrm{hexane}$ gave $43.2 \mathrm{~g}(62 \%)$ of colourless crystals. The mother liquors were purified by FC (AcOEt/hexane

5:5 to 7:3): $5 \mathrm{~g}(7.2 \%)$ of crystals. M.p. 67.5-68.5 ${ }^{\circ}$. IR (film): 3368, 3031, 2928, 2870, 1721, 1496, $1454 .{ }^{1} \mathrm{H}-\mathrm{NMR}$ $\left(\mathrm{CDCl}_{3}, 200 \mathrm{MHz}\right): 7.30\left(s, 5\right.$ arom. 3及-(6-Amino-9H-purin-9-yl) cyclobutane-1 $\beta$-methanol (cis-36). A soln. of cis-34 ( $500 \mathrm{mg}, 1.09 \mathrm{mmol}$ ) and aq. HF-urea ( $3 \mathrm{ml}, 9 \mathrm{mmol}$ ) in THF $\left(10 \mathrm{ml}\right.$ ) was stirred for 15 h at r.t. TLC (AcOEt/MeOH 2:8): $R_{\mathrm{f}} 0.12$. The mixture was neutralized with $\mathrm{NaHCO}_{3}$ and evaporated. Purification by $\mathrm{FC}(\mathrm{AcOEt} / \mathrm{MeOH} 9: 1)$ afforded $\mathrm{cis}-\mathbf{3 6} / \mathrm{NaF}$. FC (hydrophobic silica gel) with $\mathrm{H}_{2} \mathrm{O}$ gave NaF and then with MeOH cis- 36 ( 60 mg ). Glassy solid. UV (EtOH, $\left.0.5 \cdot 10^{-4} \mathrm{~mol} / \mathrm{l}\right): 206(16580), 262(11160) .^{l} \mathrm{H}-\mathrm{NMR}\left(\mathrm{CD}_{3} \mathrm{OD}, 200 \mathrm{MHz}\right): 8.22(s, \mathrm{H}-\mathrm{C}(2), \mathrm{Ade}) ; 8.18(s, \mathrm{H}-\mathrm{C}(8)$, Ade); 4.95 (quint., $\mathrm{H}-\mathrm{C}(3)$ ); $3.62\left(\mathrm{~s}, \mathrm{CH}_{2} \mathrm{OH}\right) ; 2.55\left(m, \mathrm{H}_{\beta}-\mathrm{C}(2), \mathrm{H}_{\beta}-\mathrm{C}(4)\right) ; 2.40\left(\mathrm{~m}, \mathrm{H}_{\alpha}-\mathrm{C}(2), \mathrm{H}-\mathrm{C}(1)\right.$, $\left.\mathrm{H}_{\alpha}-\mathrm{C}(4)\right) \cdot{ }^{13} \mathrm{C}-\mathrm{NMR}\left(\mathrm{CD}_{3} \mathrm{OD}, 50 \mathrm{MHz}\right): 157.20(\mathrm{C}(6)$, Ade); $153.92(\mathrm{C}(2), \mathrm{Ade}) ; 149.10$ (C(4), Ade); 141.22 (C(8), Ade); $111.60(\mathrm{C}(5)$, Ade $) ; 66.05\left(\mathrm{CH}_{2} \mathrm{OH}\right) ; 46.73(\mathrm{C}(3)) ; 35.57(\mathrm{C}(2), \mathrm{C}(4)) ; 31.84(\mathrm{C}(1))$. FAB-MS: 242 $\left([M+\mathrm{Na}]^{+}\right), 220\left([M+\mathrm{H}]^{+}\right), 188\left([M-\mathrm{MeOH}]^{+}\right), 136\left([\mathrm{Ade}+\mathrm{H}]^{+}\right)$.

3及-(6-Amino-9 H-purin-9-yl) cyclobutane-l $\alpha$-methanol (trans-36). As described for cis-36, trans-34 (500 mg, 1.09 mmol ) afforded trans- $36(60 \mathrm{mg})$. Glassy solid. UV ( $\mathrm{EtOH}, 0.5 \cdot 10^{-4} \mathrm{~mol} / \mathrm{l}$ ): 206 (16250), 262 (11056). $\left.{ }^{1} \mathrm{H}-\mathrm{NMR}\left(\mathrm{CD}_{3} \mathrm{OD}\right), 200 \mathrm{MHz}\right): 8.25(\mathrm{~s}, \mathrm{H}-\mathrm{C}(2)$, Ade); 8.16 ( $s, \mathrm{H}-\mathrm{C}(8)$, Ade); 5.15 (quint., H-C(3)); $3.62(s$, $\left.\mathrm{CH}_{2} \mathrm{OH}\right) ; 2.60\left(m, \mathrm{H}_{\beta}-\mathrm{C}(2), \mathrm{H}_{\beta}-\mathrm{C}(4)\right) ; 2.45\left(m, \mathrm{H}_{x}-\mathrm{C}(2), \mathrm{H}-\mathrm{C}(1), \mathrm{H}_{\mathrm{x}}-\mathrm{C}(4)\right){ }^{13} \mathrm{C}-\mathrm{NMR}\left(\mathrm{CD}_{3} \mathrm{OD}, 50 \mathrm{MHz}\right):$ $157.3\left(\mathrm{C}(6)\right.$, Ade) ; $153.90(\mathrm{C}(2)$, Ade $) ; 149.20\left(\mathrm{C}(4)\right.$, Ade) ; $141.44\left(\mathrm{C}(8)\right.$, Ade); $112.40\left(\mathrm{C}(5)\right.$, Ade); $66.21\left(\mathrm{CH}_{2} \mathrm{OH}\right)$; $48.5(\mathrm{C}(3)) ; 35.75(\mathrm{C}(2), \mathrm{C}(4)) ; 31.80(\mathrm{C}(1))$. FAB-MS: $242\left([M+\mathrm{Na}]^{+}\right), 220\left([M+\mathrm{H}]^{+}\right), 188\left([M-\mathrm{MeOH}]^{+}\right)$, $136\left([\text { Ade }+\mathrm{H}]^{+}\right)$.

Oligonucleotides. 1. Phosphorylation. A typical experiment was performed as follows: Cyclobutanemethanol $22(0.25 \mathrm{mmol}, 156.4 \mathrm{mg})$ was co-evaporated with pyridine to remove traces of $\mathrm{H}_{2} \mathrm{O}$ and phosphorylated with 2-chlorophenyl bis(benzotriazol-1-yl) phosphate ( $1.00 \mathrm{ml}, 0.25 \mathrm{~m}$ ) in THF at r.t. for 30 min (activated nucleotide) [12]. This intermediate, which can be kept in soln. for several $h$, was further processed in situ.
2. Assembling of the Nucleotides on a Solid Phase. The $3^{\prime}$-[ $5^{\prime}$-(monomethoxytrityl)- $N^{6}$-benzoyladenosyl)-suc-cinyl-amidomethyl-polystyrene ( $1 \%$ DVB cross-linked; 11.5 mg , functionalization, $2.24 \mu \mathrm{~mol}$ ) [13] was subjected to the following washing ( $3 \mathrm{ml} / \mathrm{min}$ ) and reaction procedures: $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{i}-\mathrm{PrOH} 85: 15(3 \mathrm{~min})$; MeOTr cleavage: 1 m $\mathrm{ZnBr}_{2}, 0.02 \mathrm{M} 1,2,4$-triazole in $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{i}-\mathrm{PrOH} 85: 15$ ( $1.5-2 \mathrm{~min}$ ) [14]; $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{i}-\mathrm{PrOH} 85: 15$ (3 min); 0.5 m $\left(E t_{3} \mathrm{NH}\right) \mathrm{OAc}$ in DMF ( 3 min ); $\mathrm{MeCN}\left(<0.005 \% \mathrm{H}_{2} \mathrm{O} ; 3 \mathrm{~min}\right) ; \mathrm{N}_{2}$ flow, $50^{\circ}(10 \mathrm{~min})$; coupling: $64 \mu l$ of activated carba-nucleotide ( $16 \mu \mathrm{~mol}$ ) and $6.4 \mu$ of $N$-methylimidazole $(80 \mu \mathrm{~m}), 12-15 \mathrm{~min}, 50^{\circ}$, no flow, MeCN ( 4 min ). This solid-phase process was repeated seven times. Yield per coupling step: $80-87 \%$, giving $0.6 \mu \mathrm{~mol}$ or 46 OD units calculated yield.

The oligomer was cleaved from the carrier and the protecting groups were removed by sequentially reacting the resin with lm tetramethylguanidinium 2-nitrobenzaldehyde oximate in $200 \mu \mathrm{l}$ of $95 \%$ pyridine during 7 h at $60^{\circ}$ and with $0.8 \mathrm{ml} 33 \% \mathrm{NH}_{3} / \mathrm{H}_{2} \mathrm{O}$ for 24 h at $60^{\circ}$. The mixture was extracted 3 times with $\mathrm{Et}_{2} \mathrm{O}$ ( 2 ml each), the aq.
phase applied to a Biogel P4 ( $50-100 \mathrm{mesh}$ ) column ( $3 \times 26 \mathrm{~cm}$ ), and the product eluted with $\mathrm{H}_{2} \mathrm{O}$. Fractions were checked for correct size of the oligomer and homogeneity by polyacrylamide gel electrophoresis with 12 or $20 \%$ acrylamide on 1-mm layers in 5 M urea and $E=37 \mathrm{~V} / \mathrm{cm}$ or by capillary electrophoresis. No further purification was usually needed, but due to low coupling yields with 22 , additional fractionation was performed on a Mono $Q$ $H R 5 / 5$ anion exchanger. The applied gradient was: $A=10 \mathrm{~mm} \mathrm{NaOH}, 0.05 \mathrm{~m} \mathrm{NaCl} ; B=10 \mathrm{~mm} \mathrm{NaOH}, 2 \mathrm{~m} \mathrm{NaCl}$; $0 \% B \rightarrow 40 \% B$ linear within 45 min . Fractions homogeneous in electrophoresis were checked with electrosprayionization or laser-ionization desorption MS for the presence of the expected oligomer and were appropriately pooled and desalted on a Biogel P4 column. Thus, $10 O D$ 's (optical-density units at 259 nm ) of octamer 24 and 7 $O D$ 's of the heptamer were isolated.
