Then, 0.10 mL of a 1.72 M hexane solution of $n$-butyllithium was added via syringe, and the mixture was stirred for 1 h . It was warmed to room temperature overnight and quenched with $\mathrm{H}_{2} \mathrm{O}$. The aqueous layer was extracted with pentane, and the organic portions were combined, dried over $\mathrm{MgSO}_{4}$, filtered, and evaporated. The resulting brown oil was eluted through a short silica gel plug with pentane to afford $11.0 \mathrm{mg}(75 \%)$ of ( $E$ )-2,2-dimethyl-6-phenyl-3-hexene: oil, separated on silica gel 60 F254, $2 \%$ ether-hexane, $R_{f}=0.58 ; \mathrm{m} / \mathrm{e}$, exact mass for $\mathrm{C}_{14} \mathrm{H}_{20} 188.156$, found 188.1565 ; error $=2.6 \mathrm{ppm}$; IR (neat, $1 / \mathrm{cm})(t-\mathrm{Bu}) 1380,(\mathrm{C}=\mathrm{C}) 1670$ 270 MHz NMR ( $\left.\mathrm{CDCl}_{3}, \mathrm{ppm}\right) 7.3-7.13(5 \mathrm{H}, \mathrm{m}), 5.44(1 \mathrm{H}, \mathrm{dd}, J=$ $15.6 \mathrm{~Hz}), 5.34(1 \mathrm{H}, \mathrm{dt}, J=15.6,5.8 \mathrm{~Hz}), 2.65(2 \mathrm{H}, \mathrm{dd}, J=7.3,9.6$ $\mathrm{Hz}), 2.28-2.24(2 \mathrm{H}, \mathrm{m}), 0.97(9 \mathrm{H}, \mathrm{s})$.

Oxidation of 2 with mCPBA. A solution of 2 in 1 mL of $\mathrm{CDCl}_{3}$ (+repared as above from 5.6 mg of polymer 3 ) was cooled to $-78^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$, and $182 \mu \mathrm{~L}$ of a $100 \mathrm{mg} / \mathrm{mL} \mathrm{CDCl}_{3}$ solution of $m$-chloroperbenzoic acid (Aldrich, $80-85 \%, 55 \mu \mathrm{~mol}$ ) was titrated via syringe to a colorless endpoint. Direct NMR analysis of the reaction medium showed signals corresponding to $m$-chlorobenzoic acid, a trace of trimers 4 and sulfine 17 (identified as the $E$ isomer by comparison with literature spectra ${ }^{22}$ ) in the molar ratio 9.5:1:8.

Reaction of 2 with Diphenylketene. Two milliliters of a $\mathrm{CDCl}_{3}$ solution of 2 (generated as above from 12 mg of 3 ) were treated under $\mathrm{N}_{2}$ with 0.15 mL of a 0.50 M solution of diphenylketene ${ }^{26}$ in benzene. After the

Contribution from the Department of Chemistry and Biochemistry, University of California, Los Angeles, California 90024. Received October 15, 1985

#### Abstract

Syntheses and crystal structures are reported for a new class of hosts, their complexes, and their precursors. The cryptahemispherands 5-8 are composed of molecular modules that are half spherand $\mathbf{1}$ and half cryptand 3 . They were synthesized by the reactions of diacid chloride 20 with cyclic diamines 21-23 to produce diamides 13-16, reduction of which gave the desired hosts 5-8. These diamines were best purified, stored, and handled through their respective hydroborane complexes, 9-12. Hosts 6 and 7 are diastereomeric, as are diamides 14 and 15 and hydroborane complexes 10 and 11. Diamines 6 and 7 equilibrate rapidly at $25^{\circ} \mathrm{C}$ probably by ring inversion of the methoxyl groups to give a $5: 1$ ratio of 6 over 7. Diamides 14 and 15 equilibrate readily at $90^{\circ} \mathrm{C}$ to give only 14 in detectable amounts. Hydroborane complexes 10 and 11 do not equilibrate at $90^{\circ} \mathrm{C}$. Cryptahemispherands 5,6 , and 8 formed a variety of complexes with the alkali metal cations, diamides 14 and 16 exhibited a low level of binding power, and hydroborane complexes 10 and 12 had no detectable affinity for the alkali metal cations. Hemispherand 17 was synthesized for comparison purposes. Crystal structures were determined for the isomeric diamides 14 and 15 , for hydroborane complex 9 , and for alkali cation complexes $5 . \mathrm{NaB}(\mathrm{Ph})_{4}, 6 \cdot \mathrm{KSCN}, 8 . \mathrm{NaSCN}, 8 \cdot \mathrm{KSCN}$, and $8 \cdot \mathrm{CsClO}_{4}$. The trisanisyl modules of all eight compounds possess the same preorganized conformation, with the unshared electron pairs of the three methoxyl groups turned inward and the methyl groups outward. The potential cavities of 9,14 , and $\mathbf{1 5}$ are filled with inward-turned hydrogens of the ethylene bridges. In the alkali metal ion complexes, the unshared electron pairs of the heteroatoms are all turned inward toward the guest metal ion. The use of CPK molecular models in predicting the structures of complexes is evaluated.

Structures 1-4 portray a prototypical spherand, a hemispherand, a cryptand, and a chorand, respectively. In prior studies, we compared the binding abilities of these types of hosts toward the alkali metal ions in $\mathrm{CDCl}_{3}$ at $25^{\circ} \mathrm{C}$. We concluded that the spherands $>$ cryptands $>$ hemispherands $>$ chorands $>$ podands $>$ solvents in their binding power toward complementary alkali metal ions. The same order applies to their states of organization

[^0]for binding and being unsolvated prior to complexation. Extensive examinations of the relationships between structure and binding provided the corollary that the highest specificities in alkali metal ion binding were associated with the most highly preorganized systems. ${ }^{2,3}$

The anisyl groups of the hemispherands are self-organizing, whereas the bridging ethyleneoxy groups can turn their unshared electron pairs and methylene groups either inward or outward, depending on the demands of solvent or guests. ${ }^{4}$ Because of this

blend of rigidity and flexibility, the hemispherands proved to be a particularly good vehicle for studies of structure-binding correlations. Additionally, the hemispherands provide high rates of complexation-decomplexation, chemical stability, and good correlations between predictions based on CPK molecular model examination and their solution and crystal structures. ${ }^{5.6}$

This paper reports the synthesis of the cryptahemispherands 5-8, hydroborane complexes 9-12, precursors 20 and 21, several alkali metal-ion complexes of hosts 5-8, and eight crystal structures of these macrobicyclic systems. In CPK molecular models, these compounds appear to be more highly preorganized than the cryptands but less than the spherands. We, therefore, anticipated that they should be very strong and specific binders of the alkali metal ions. The diazahemispherand 17 was also prepared for comparison purposes. A companion paper compares the free energies of binding by the cryptands and cryptahemispherands of the alkali metal picrate salts in $\mathrm{CDCl}_{3}{ }^{7,8}$

## Results and Discussion

Synthesis. The critical ring-closing reactions to form bicyclic diamides 13-16 involved condensation of diacid chloride $\mathbf{2 0}$ with diazachorands 21-23 by procedures similar to those used to prepare the cryptands. ${ }^{9-11}$ Diacid 19 has been reported ${ }^{12}$ and was converted to 20 with $\mathrm{SOCl}_{2}(72 \%)$. The experimental part records an improved procedure for making diamine 21.13 Di amines 22 and 23 were purchased. ${ }^{14}$ The acylations of 20 were conducted at $15-20^{\circ} \mathrm{C}$ in benzene by double high dilution addition of each component to a benzene solution of $\mathrm{Et}_{3} \mathrm{~N}$. The yields of the cyclic diamides decreased with decreasing ring size. Thus 16 was prepared in $90 \%$ yield, a mixture of 14 and 15 in $72 \%$, and

13 in $47 \%$ yield. As expected, the retention volumes of these cyclic diamides upon purification by gel permeation chromatography increased with decreasing ring size.

Diamides 14 and 15 are geometrical isomers which in principle can interconvert provided all three methoxyl groups ring invert. Examination of CPK molecular models suggested that these isomers should be isolable at room temperature but might interconvert at higher temperatures. In practice, 14 and 15 were separated by HPLC, and 14 was found to dominate in the mixture by a factor of $2: 1$ when the ring closure was run below $25^{\circ} \mathrm{C}$ and by a factor of $12: 1$ if the reaction temperature was allowed to reach $50^{\circ} \mathrm{C}$. Molecular model examination indicated that the isomer with the longer bridge syn to the two methoxyl groups should be less strained than that with the longer bridge syn to the single methoxyl group. Furthermore, in the models of 14 and 15 , the methyls of the methoxy groups on the flanking benzenes of 14 were forced less than those of 15 into the shielding cone of the central benzene, and the methyl on the oxygen of the central benzene was forced more into the shielding cone of the flanking benzene rings. Comparison of the ${ }^{1} \mathrm{H}$ NMR spectra of the two isomers showed that in the dominant isomer, the outer methoxy signal was downfield (less shielded) and the inner methoxy signal was upfield of the corresponding signals of the subordinate isomer. This allowed the dominant isomer to be assigned structure 14 and the subordinate isomer structure 15. This assignment was confirmed by crystal-structure determination of both isomers (see below).

Although $\mathrm{LiAlH}_{4}$ or $\mathrm{H}_{3} \mathrm{~B} \cdot$ THF reduction of model compound $o$-methoxy- $N, N$-dimethylbenzamide went well under a variety of conditions, the cyclic diamides produced many side products. Furthermore, the diamines produced were unstable in chromatography on silica gel. Diamide 13 was successfully reduced only with diborane generated in situ $\left(\mathrm{NaBH}_{4}+\mathrm{F}_{3} \mathrm{~B} \cdot \mathrm{O}(\mathrm{Et})_{2}+\mathrm{THF}\right)^{15}$ at $-78^{\circ} \mathrm{C}, 14$ and 15 as a mixture with the same reagent at 25

[^3]${ }^{\circ} \mathrm{C}$, and 16 with $\mathrm{H}_{3} \mathrm{~B} \cdot \mathrm{~S}\left(\mathrm{CH}_{3}\right)_{2}{ }^{16}$ The products were isolated as their hydroborane complexes 9-12 (69-78\%). These complexes proved stable to chromatographic purification on silica gel. The ratio of $\mathbf{1 0 : 1 1}$ produced in various reductions varied between 5 to 1 and 2 to 1 , with $\mathbf{1 0}$ as the dominant isomer. Complexes 9-12 were crystalline and could be stored ( 9 only at $-78^{\circ} \mathrm{C}$ ). Their ${ }^{1} \mathrm{H}$ NMR spectra suggested the compounds possessed a mirror plane, which indicates that both moles of $\mathrm{BH}_{3}$ are complexed either on the outside or on the inside of the cavity. Since none of the cavities are larger enough to accommodate 2 mol of $\mathrm{BH}_{3}$, the complexing electron pairs on the nitrogens must face outward to coordinate the $\mathrm{BH}_{3}$ on the surfaces of the macrocycles. This conclusion was confirmed by the crystal structure determination of 9 (see below).

Although these complexes were decomposed as expected, ${ }^{17}$ upon treatment with hydrochloric acid in THF at reflux, this temperature was high enough to partially cleave the benzyl-nitrogen bonds and to isomerize 7 to 6 . The use of tetramethylenediamine in the isolation was also unsatisfactory, since excess reagent and temperatures higher than $50^{\circ} \mathrm{C}$ were required. ${ }^{17}$ The hydroborane complexes 9 and 12 were, therefore, oxidatively cleaved with $\mathrm{I}_{2}{ }^{18}$ in the presence of $\mathrm{Mg}(\mathrm{OAc})_{2}$ buffer ( NaOAc provided unwanted host $\cdot \mathrm{Na}^{+}$complexes). The products in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution were washed with aqueous $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{NOH}$ to give unprotonated and noncrystalline cryptahemispherands, 5 and 8 , in $78 \%$ and $94 \%$ yields, respectively. These hosts slowly decomposed even in the absence of light and air at $0^{\circ} \mathrm{C}$ and were, therefore, best freed from their borane complexes just before use. Oxidative decomplexation of $\mathbf{1 0}$ gave a product whose ${ }^{1} \mathrm{H}$ NMR spectrum indicated it might be $6 \cdot \mathrm{I}^{+} \mathrm{I}^{-}$. The spectrum resembled that produced when $\mathrm{I}_{2}$ and 5 were mixed in $\mathrm{CDCl}_{3}$ to give what is probably $5 \cdot \mathrm{I}^{+} \mathrm{I}^{-}$, identified by its FABMS $\left(\mathrm{M}^{+}+\mathrm{I}^{+}\right)$peak. The cryptands have been found to form stable complexes with $\mathrm{I}_{2}{ }^{19}$ When 10 was held at reflux in hydrochloric acid-THF, the ${ }^{1}$ H NMR spectrum of the product showed it to be a mixture of 6 and 7 and a minor amount of material produced by benzyl-nitrogen cleavage. The mixture was stirred with aqueous KSCN to give $6 \cdot \mathrm{KSCN}$, identified by crystal-structure determination. Oxidative decomplexation of 11 with $\mathrm{I}_{2}$ gave a product whose ${ }^{1} \mathrm{H}$ NMR spectrum resembled those observed from products similarly produced from 9 and 12 but more complicated. In addition to spectra due to 6 and 7, less symmetrical isomers also seemed to be present. Treatment of the mixture with KSCN provided $6 \cdot \mathrm{KSCN}$. We conclude that host compounds 6 and 7 interconvert at room temperature at rates rapid on the human time scale. Complexes $6 \cdot \mathrm{Li}^{+}$picrate, $6 \cdot \mathrm{Na}^{+}$picrate, and $6 \cdot \mathrm{~K}^{+}$picrate were prepared and characterized through their ${ }^{1} \mathrm{H}$ NMR spectra. Although $6 \cdot \mathrm{Na}^{+}$ picrate could be purified by chromatography, $6 \cdot \mathrm{Li}^{+}$picrate and $6 \cdot \mathrm{~K}^{+}$picrate exchanged their metal ions for sodium ions on thick-layer plates of silica gel. Free hosts 8-11 could not be chromatographed without complexing the sodium salts absorbed on stationary phases.

The cryptahemispherands and their complexes were found by ${ }^{1} \mathrm{H}$ NMR experiments to behave somewhat similarly to the cryptands when their metal ion complexes were treated with acid. ${ }^{20}$ For example, when $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{D}$ was added to a $\mathrm{CDCl}_{3}$ solution of $8 \cdot \mathrm{Na}^{+}$picrate, the material decomplexed and formed the diprotonated host ( ${ }^{1} \mathrm{H}$ NMR spectral experiments). In a similar experiment with $6 \cdot \mathrm{Li}^{+}$picrate, decomplexation also occurred. However, attempts to wash the lithium salts away with water resulted in considerable loss of protonated host due to its dissolution in the aqueous phase. Addition of $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{D}$ to 5 in $\mathrm{CDCl}_{3}$ at $25^{\circ} \mathrm{C}$ gave the cyclic diammonium salt, which proved to be

[^4]somewhat soluble in $\mathrm{D}_{2} \mathrm{O}$. When a $\mathrm{CDCl}_{3}$ solution of 5 was shaken with $\mathrm{D}_{2} \mathrm{O}\left(\mathrm{pH} \sim 5\right.$ due to $\left.\mathrm{D}_{2} \mathrm{CO}_{3}\right), 5$ became protonated, presumably on the outside of the cavity. When excess 3 N aqueous HCl was added to a $\mathrm{CDCl}_{3}$ solution of 5 , the internally diprotonated compound was formed, which gave broad ${ }^{1}$ H NMR signals. When the excess acid was washed away, the signals sharpened. Stirring the resulting solution at $25^{\circ} \mathrm{C}$ for 12 h with 6 N aqueous tetramethylammonium hydroxide failed to deprotonate the amines. This result is similar to that observed for [1.1.1] cryptand and [2.1.1] cryptand. ${ }^{21,22}$ Although the cavity of $\mathbf{5}$ is larger than that of either of those cryptands, it is small enough to hinder fast proton transfer to and from the nitrogens inside the cavity. These experiments indicated that the use of strong acid to convert the hydroborane complexes 9-12 to free hosts 5-8 is troublesome.

Diazahemispherand 18 was prepared for comparison purposes by condensing diacid chloride 20 with $\mathrm{O}\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)_{2}$ to give diamide 18 ( $75 \%$ ), which was reduced to 17 with $\mathrm{LiAlH}_{4}$ in THF at reflux. Various hydroborane reducing agents gave only bad mixtures of products.

Isomerization of Diamides 14 and 15. When bicyclic diamide 15 was held at reflux for 1 h in anhydrous THF ( $66^{\circ} \mathrm{C}$ ), 'H NMR spectral measurements showed $80 \%$ had isomerized to 14. A similar experiment run in $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}$ at $90^{\circ} \mathrm{C}$ for 15 min provided $86 \%$ isomerization, whereas prolonged heating ( 5 h ) gave $>95 \%$ conversion of $\mathbf{1 5}$ to 14 (based on a $5 \%$ detection limit for 15). When 14 was submitted to 5 h of heating at $90^{\circ} \mathrm{C}$ in $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}$, no $\mathbf{1 5}$ could be detected in its ${ }^{1} \mathrm{H}$ NMR spectrum. From these experiments, the first-order rate constant for $15 \rightarrow 14$ is estimated to be $\sim 2.3 \times 10^{-3} \mathrm{~s}^{-1}\left(\Delta G^{\ddagger} \sim 26 \mathrm{kcal} \mathrm{mol}^{-1}\right)$, and $14 \rightarrow \mathbf{1 5}$ is $<5.6 \times 10^{-7} \mathrm{~s}^{-1}\left(\Delta G^{\ddagger}>32 \mathrm{kcal} \mathrm{mol}^{-1}\right)$. Since the same transition state is involved in these two reactions, these values suggest that $\Delta\left(\Delta G^{\circ}\right)$ for the conversion of $15 \rightarrow \mathbf{1 4}$ is at least $-6 \mathrm{kcal} \mathrm{mol}^{-1}$ at $90^{\circ} \mathrm{C}$. When hydroborane complexes 10 and 11 were each heated at $90^{\circ} \mathrm{C}$ in $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}$ for 5 h , no isomerization could be detected.

During the syntheses described in the last section, acid-catalyzed hydrolysis of hydroborane complex 10 at $66^{\circ} \mathrm{C}$ and oxidative cleavage of hydroborane complex 11 at $25^{\circ} \mathrm{C}$ both led to mixtures of diamines 6 and 7 in which isomer 6 dominated. Additionally, reduction of diamide 15 with diborane at $25^{\circ} \mathrm{C}$ gave mixtures of hydroborane complexes 10 and 11 containing $20-50 \%$ of the former isomer. Since 10, 11, and 15 were stable to isomerization under the conditions of the above experiments, the results point to 6 and 7 occurring as rapidly interconverting intermediates in the conversions of diamide 14 and $\mathbf{1 5}$ to hydroborane complexes, 10 and 11. The results suggest that at equilibrium at $25^{\circ} \mathrm{C}, 6$ dominates over 7 by a factor of about 5 .

These experiments taken in sum indicate the probable order of stability with respect to ring inversion of the three methoxyl groups to be the following: hydroborane complexes $>$ diamides $>$ diamines. This order correlates with expectations based on CPK model examinations of the six compounds involved, coupled with the crystal structure results. Coordination of the outward-turned electron pairs of the two nitrogen atoms to $\mathrm{BH}_{3}$ elongates the molecules along their N to N axis and shrinks them in the dimensions perpendicular to the N to N axis, especially near the mirror plane. Ring inversion requires swelling of the molecules in the region close to their mirror planes to allow the methyl groups to pass through the centers of the macrobicycles. Thus $\mathrm{N} \cdot \mathrm{BH}_{3}$ complexation opposes ring inversion. In the diamides, 14 and 15, both CPK models and the crystal structures indicate that the $\mathrm{C}=\mathrm{O}$ oxygens are turned outward away from the cavity. The delocalization of electrons in the amide bond requires near coplanarity of the attached substituents. To ring invert 14 or 15 , the $\pi$-orbitals of the $\mathrm{C}=\mathrm{O}$ groups and the nitrogen lone pair must uncouple. Thus the two diamides resist ring inversion at ambient temper-

[^5]ature. In contrast, the two bridges of the diamines 6 and 7 are conformationally more flexible. Accordingly, 6 and 7 adapt more readily to the steric requirements of ring inversions of the three methoxyl groups at ambient temperature.

Qualitative Complexation Experiments. In contrast to the cryptahemispherands 5,6 , and 8 , which were difficult to handle because of their propensity for complexing $\mathrm{Na}^{+}$, the diamides 14 and 15 and the hydroborane complexes 10 and 12 were very poor binders of the alkali metal ions. When solutions of 14 or 16 in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ were shaken with aqueous solutions of $\mathrm{Li}^{+}, \mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{Rb}^{+}$, or $\mathrm{Cs}^{+}$picrates, 14 extracted only traces of potassium picrate, and 16, only traces of cesium picrate. When submitted to the usual picrate salt extraction method for determining $-\Delta G^{\circ}$ values at $25^{\circ} \mathrm{C}$ in $\mathrm{CDCl}_{3}$ saturated with $\mathrm{D}_{2} \mathrm{O}, 14$ and 16 gave $-\Delta G^{\circ}$ values of $<6 \mathrm{kcal} \mathrm{mol}^{-1}$ binding free energies for all ions. ${ }^{23}$ When sodium tetraphenyl borate was added as a solid to 16 in $\mathrm{CDCl}_{3}$, it dissolved, and complexation changed the methoxy proton ${ }^{1} \mathrm{H}$ NMR spectral signals by as much as 0.11 ppm . When shaken with $\mathrm{D}_{2} \mathrm{O}$, the original spectrum of free 16 was regenerated, indicating the salt decomplexed and washed into the $\mathrm{D}_{2} \mathrm{O}$ layer. The low binding power of these diamides is attributed to the repulsions between the partial positive charges on the two nitrogens (which line the cavity) and the positively charged guests. Similar attempts to complex hydroborane derivatives 10 and 12 gave completely negative results. Molecular model examinations of $\mathbf{1 0}$ and $\mathbf{1 2}$ indicate that formation of cavities in these molecules involves considerable strain.

Crystal Structures. Crystal structures of the following eight representative macrobicyclic systems were obtained: diamides 14 and 15; hydroborane complex 9; and alkali metal complexes $5 \cdot \mathrm{NaB}(\mathrm{Ph})_{4}, 6 \cdot \mathrm{KSCN}, 8 \cdot \mathrm{NaSCN}, 8 \cdot \mathrm{KSCN}$, and $8 . \mathrm{CsClO}_{4}$. Common to all eight crystal structures is the conformational arrangement of the trisanisyl module. The unshared electron pairs of the three methoxy oxygens all face inward toward the potential cavity, which is filled with either methylene hydrogens of the bridges or the encapsulated metal ions. The methyl groups of the methoxyls all face outward away from the potential cavity, those attached to the flanking benzenes being syn to one another and anti to that of the central benzene. Throughout this paper, all structures are viewed from the face of the macroring that places the two $\mathrm{OCH}_{3}$ groups nearer to the eye. The up-down-up arrangement of the $\mathrm{OCH}_{3}$ groups appears to be a property of the molecular module to which the bridging $\mathrm{CH}_{2} \mathrm{OCH}_{2}$ and $\mathrm{CN}(\mathrm{C}-$ $\left.\mathrm{H}_{2}\right)_{2}$ units adapt, depending on whether and how the hosts are complexed. Thus the spherand-like module is preorganized for binding, whereas the cryptand-like module must conformationally reorganize to allow guests to enter the cavity. ${ }^{8}$ These results further substantiate the generalizations that relate the class of host to the state of conformational organization of the cavity prior to the complexing act. Thus the spherands are totally preorganized, the hemispherands and cryptahemispherands are partially preorganized, and the cryptands and chorands are not conformationally preorganized for binding. ${ }^{2}$ The spherands, hemispherands, and cryptahemispherands were all designed through examination of CPK molecular models. These eight crystal structures further illustrate the utility of these models for designing new hosts and for predicting their states of preorganization.

In Charts I and II ordinary drawings of the macrocycles are coupled with stereodrawings of the eight crystal structures in which the counterions are omitted unless they coordinate the guest. ${ }^{8}$ Only an overview of the structural features are presented here. The details and many interesting comparisons will be published elsewhere.

A comparison of the crystal structures of diamides 14 and 15 indicates why the former is the more stable. The amide modules in the two molecules are essentially normal. In 14, the average distance of the two N atoms from the plane of their three attached carbons is $0.06 \AA$; in 15 that distance is $0.08 \AA$. For both isomers,

${ }^{a} \mathrm{~K}^{+}$is contact ion-paired to N of $\mathrm{NCS}^{-}, \mathrm{N} \cdots \mathrm{M}^{+}$distance, $3.12 \AA$. ${ }^{b} \mathrm{H}_{2} \mathrm{O}(1 \mathrm{~mol})$ ligates the $\mathrm{K}^{+}, \mathrm{K}^{+} \ldots \mathrm{OH}_{2}$ distance, $3.44 \AA .{ }^{c} \mathrm{H}_{2} \mathrm{O}$ (1 mol ) ligates the $\mathrm{Cs}^{+}, \mathrm{Cs}^{+} \ldots \mathrm{OH}_{2}$ distance, $3.56 \AA$. ${ }^{d}$ The identity of these pairs of values is associated with the crystallographic mirror symmetry in the molecule. "Calculated assuming the O -atom radius equals 1.40 , and the N -atom radius is $1.50 \AA$.
the distance of the N from the $\mathrm{C}-\mathrm{C}=\mathrm{O}$ plane is $0.00 \AA$, and the bond lengths and angles are not far from being normal. However, the $\mathrm{N} \cdots \mathrm{N}$ distance in 14 at $6.48 \AA$ is greater than in 15 at $5.45 \AA$, which reflects the different effective lengths of the bridges syn to the two methoxyl groups in the two isomers. In the more stable isomer 14 the $\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{O}$ conformations are more staggered than they are in 15 . The longer bridge in 15 is more folded and compressed than in 14. In effect, 14 is more stable than 15 because the longer bridge in 14 is located on the same side of the macroring as the two methoxyl groups, where the route required to span the two nitrogens is longer than on the opposite side.

The crystal structure of hydroborane adduct 9 provides a $\mathrm{N} \ldots \mathrm{N}$ distance of $5.96 \AA$ and aryl-aryl dihedral angles of $67^{\circ}$. The $N-B$ bond lengths are $1.58 \AA$, close to the average $\mathrm{C}-\mathrm{N}$ bond lengths of $1.57 \AA$. These bond lengths differ from the N-B distance of $1.66 \AA$ and the $\mathrm{N}-\mathrm{C}$ distances of $1.52 \AA$ observed in the crystal structure of the bishydroborane complex of [2.2.2] cryptand. ${ }^{24}$ The fact that the $\mathrm{BH}_{3}$ groups lie outside the cavity forces the $\mathrm{N}-\mathrm{C}$ bonds to be directed inward, which in turn leads to congestion of the two bridges, a pushing apart of the two nitrogens, and an expansion of the $\mathrm{Ar}-\mathrm{Ar}$ dihedral angles as compared to complexes where the guests occupy the cavity.

Table I lists some structural parameters of the five cryptahemispherand complexes of the alkali metal ions. Of these, $5 \cdot \mathrm{Na}^{+}$, $6 \cdot \mathrm{~K}^{+}$, and $8 \cdot \mathrm{Cs}^{+}$are very stable complexes based on picrate salt binding studies in $\mathrm{CDCl}_{3} .^{7}$ The sodium ion in $5 \cdot \mathrm{Na}^{+}$exhibits strong interactions with all of its ligands. The $\mathrm{Na}^{+} \ldots \mathrm{N}$ and $\mathrm{Na}^{+} \ldots \mathrm{O}$ distances are all close to the standard values of $2.66 \AA$ and 2.35 $\AA$, respectively. ${ }^{25}$ There are no interactions with external ligands; molecular models indicate there is little room for any. The Ar-Ar dihedral angles are $\sim 55^{\circ}$. The diameter of $\mathrm{Na}^{+}$bound to the seven heteroatoms is $2.14 \AA$, which is greater than the diameter of $1.75 \AA$ for $\mathrm{Na}^{+}$bound to six ligands in $1 \cdot \mathrm{Na}^{+} .{ }^{2}$ As expected from the short bridges, the $\mathrm{N} \cdots \mathrm{N}$ distance of $4.64 \AA$ is shorter than is observed in any of the other eight crystal structures.

The potassium ion in $6 \cdot \mathrm{~K}^{+}$interacts strongly with seven of its eight ligands. The $\mathrm{K}^{+} \ldots \mathrm{N}$ distance of $3.09 \AA$ is not far from the standard value of $2.83 \AA .{ }^{25}$ For reasons not understood, the central
(24) Metz, B.; Moras, D.; Weiss, R. J. Chem. Soc. Perkin Trans. 2 1976, 423-429.
(25) These values were obtained by adding the ionic radii of the metal ions to the van der Waals radii of the ligating atoms. Values were taken from Pauling, L. C. Nature of the Chemical Bond, 2nd ed.; Cornell: Ithaca, New York, 1940; pp 189, 350.

8. $\mathrm{K}^{+}$

methoxy oxygen is $3.21 \AA$ from the $\mathrm{K}^{+}$, which is also reflected in the high aryl-aryl dihedral angle of $63^{\circ}$. The N of the thiocyanate coordinates the $\mathrm{K}^{+}$in complex in the middle of the area defined by the two syn methoxyl groups and the two oxygens of the longer bridge. The distance from $\mathrm{K}^{+}$to the N of the counterion is $3.12 \AA$, close to the $\mathrm{K}^{+} \ldots \mathrm{N}$ distance for the two neutral nitrogen ligands ( $3.09 \AA$ ).

Molecular model examination of $8 \cdot \mathrm{Na}^{+}, \mathbf{8} \cdot \mathrm{K}^{+}$, and $8 \cdot \mathrm{Cs}^{+}$ suggests good complementarity for $8 . \mathrm{Cs}^{+}$, moderate complementarity for $8 \cdot \mathrm{~K}^{+}$, and poor complementarity for $8 \cdot \mathrm{Na}^{+}$. The crystal structures of the three complexes confirmed the expectation and show how the hosts in $8 \cdot \mathrm{Na}^{+}$and $8 \cdot \mathrm{~K}^{+}$adapt to their smaller-than-ideal guests. The two $\mathrm{Na}^{+} \ldots \mathrm{N}$ distances are 3.18 and $3.64 \AA$, well-above the standard value of $2.45 \AA .{ }^{25}$ Five of the $\mathrm{Na}^{+} \ldots \mathrm{O}$ distances are between 2.53 and $2.69 \AA$, while the other two are 2.78 and $2.85 \AA$, compared to the standard distance of $2.35 \AA .{ }^{25}$ Because of spacial constraints, the cavity of $\mathbf{8}$ is unable to contract enough to allow all eight of its heteroatoms to ligate the $\mathrm{Na}^{+}$at the same time. As a consequence, the cavity diameter is not notably dissimilar from that of $\mathbf{8} \cdot \mathrm{Cs}^{+}$. This is shown by the facts that the $\mathrm{N} . . \mathrm{N}$ distances are almost identical ( $6.68 \AA$ for $8 \cdot \mathrm{Na}^{+}$and $6.67 \AA$ for $8 \cdot \mathrm{Cs}^{+}$) and the average $\mathrm{Ar}-\mathrm{Ar}$ dihedral angles are very similar ( $57^{\circ}$ for $8 \cdot \mathrm{Na}^{+}$and $56^{\circ}$ for $8 . \mathrm{Cs}^{+}$). In effect, the $\mathrm{Na}^{+}$ligates the five oxygens close to one of the nitrogens, and the cavity is unfilled except in this region. The apparent $\mathrm{Na}^{+}$diameter is $2.56 \AA$, much greater than normal. In solution, the $\mathrm{Na}^{+}$in $8 \cdot \mathrm{Na}^{+}$is undoubtedly "rattling around" in the cavity.

The host is $\mathbf{8} \cdot \mathrm{K}^{+}$adapts somewhat differently. The normal diameter of $\mathrm{K}^{+}$is large enough for all nine ligating sites to be within reach of the metal ion with a small contraction of the cavity. Thus the $\mathrm{N} . . \mathrm{N}$ distance in $8 . \mathrm{K}^{+}$shrinks to $6.36 \AA$, and the $\mathrm{Ar}-\mathrm{Ar}$ dihedral angle shrinks to an average value of $54^{\circ}$. The $\mathrm{N} \cdots \mathrm{K}^{+}$ distances are 3.22 and $3.25 \AA$ compared to the standard values of $2.83 .{ }^{25}$ The average $\mathrm{O} \cdots \mathrm{M}^{+}$distance is $2.88 \AA$ (seven values ranging only from $2.83-2.94$ ) compared to the standard value of $2.73 \AA .{ }^{25}$ These comparisons suggest that the $\mathrm{K}^{+}$ion is ligated by all nine heteroatoms to give a $\mathrm{K}^{+}$diameter of $2.96 \AA$. Water ( 1 mol ) also coordinates the $\mathrm{K}^{+}$at a $\mathrm{H}_{2} \mathrm{O} \cdots \mathrm{K}^{+}$distance of 3.44 $\AA$. Its oxygen is surrounded by the four oxygens and the two nitrogens of the bridge. A simple way to visualize the complex is to notice that the four oxygens and two nitrogens in the bridges compose a diaza-18-crown-6 whose heteroatoms are within $\pm 0.4$ $\AA$ of being coplanar. On one face of the best plane are found the three methoxy oxygens, and centered on the other face is the oxygen of the ligating water molecule.

Comparisons of the $\mathrm{N} \ldots \mathrm{Cs}^{+}$and $\mathrm{O} \ldots \mathrm{Cs}^{+}$distances in $8 . \mathrm{Cs}^{+}$with the standard values of 3.19 and $3.09 \AA$, respectively, ${ }^{25}$ show that $\mathrm{Cs}^{+}$has strong interactions with all nine ligands of the host. The two $\mathrm{N} \cdots \mathrm{Cs}^{+}$distances are 3.40 and $3.36 \AA$, whereas the $\mathrm{O} . . \mathrm{Cs}^{+}$ average distance is $3.03 \AA$, the values ranging from 2.91 to 3.15 $\AA$. Thus 8 appears to be a nearly ideal host for $\mathrm{Cs}^{+}$. It provides $\mathrm{a} \mathrm{Cs}^{+}$diameter of $3.26 \AA$. Interestingly, $8 \cdot \mathrm{Cs}^{+}$is also bound to a mol of water located in a position different from that in $8 \cdot \mathrm{~K}^{+}$. The oxygen of the water lies between the two oxygens of the syn-methoxy groups and the two oxygens of the proximate bridge, similar to where the $\mathrm{SCN}^{-}$counterion contacts $\mathrm{K}^{+}$in $6 \cdot \mathrm{~K}^{+}$.
The $\mathrm{N} \cdots \mathrm{M}^{+} \ldots \mathrm{N}$ angles provide a general measure of how much the diazacrown moiety is folded about the axis of the two nitrogens in the five metal-ion complexes. This angle would be $180^{\circ}$ in the absence of folding. In $5 \cdot \mathrm{Na}^{+}$and $6 \cdot \mathrm{~K}^{+}$, the $\mathrm{N} \cdots \mathrm{M}^{+} \ldots \mathrm{N}$ angles are both $125^{\circ}$, which provides $180^{\circ}-125^{\circ}=55^{\circ}$ of folding of the bridging ring. In $8 \cdot \mathrm{Na}^{+}, 8 \cdot \mathrm{~K}^{+}$, and $8 \cdot \mathrm{Cs}^{+}$, the folds of the bridging ring are 24,21 , and $19^{\circ}$, respectively.

A comparison of the structural parameters of the parent spherand complex $1 \cdot \mathrm{Na}^{+2}$ with those of $5 \cdot \mathrm{Na}^{+}$is instructive. The respective values are as follows: $\mathrm{Na}^{+}$diameter, $1.75 \AA$ (six ligands), $2.14 \AA$ (seven ligands); average aryl-aryl dihedral angles, 61 and $56^{\circ}$; average angle between aryl-oxygen bond and the $1,2,6$-aryl carbon plane, 1.8 and $1.8^{\circ}$; average angle of fold of aryl around the $\mathrm{O}-\mathrm{Ar}^{-} \mathrm{CH}_{3}$ axis, 4.8 and $5.4^{\circ}$; average angle between $\mathrm{CH}_{3} \mathrm{OC}$ plane and the best aryl plane, 84 and $77^{\circ}$; and the average
$\mathrm{ArOCH}_{3}$ bond angle, 114 and $113^{\circ}$ (normal angle is $118^{\circ}$ ). Taken in sum, these parameters are remarkably alike considering that half of one complex differs radically from half of the other complex.

## Experimental Section

General Methods. THF and diethyl ether were freshly distilled from sodium benzophenone ketyl just prior to use, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ from $\mathrm{CaH}_{2}$, and benzene from $\mathrm{LiAlH}_{4}$. All other solvents were dried over $3-\AA$ molecular sieves. All chemicals were reagent grade. All reactions were conducted under an argon atmosphere. Flash chromotography was carried out on silica gel 60 (E. M. Merck, particle size $0.040-0.063 \mathrm{~mm}, 230-400$ mesh ASTM). Gravity columns were packed with silica gel 60 (E. M. Merck, particle size $0.063-0.200 \mathrm{~mm}, 70-230$ mesh ASTM). Gel permeation chromatography was performed on a 20 ft by 0.375 in. (o.d.) column packed with 200 g of styragel (Waters Associates) with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ as mobile phase at flow rates of approximately 4.0 mL per min. Preparative thin-layer chromotography was effected on $0.5 \mathrm{~mm}, 1 \mathrm{~mm}$, or 2 mm silica gel plates ( $\mathrm{E} . \mathrm{M}$. Merck, $60 \mathrm{~F}_{254}$ ) or 1 mm reverse phase silica gel plates (PLKC 18F, Whatman). Thin-layer chromatography was conducted on plastic-backed precoated silica gel plates (E. M. Merck, $\mathrm{F}_{254}, 0.2 \mathrm{~mm}$ thickness) and reverse phase plates (Whatman, KC 18F, 0.2-mm thickness). High-pressure liquid chromatography was performed on a Waters Prep LC/System 500A liquid chromatograph. The compounds were purified on either one or two PrepPAK silica cartridges containing approximately 500 g of silica gel each. Melting points below $240^{\circ} \mathrm{C}$ were measured on a Thomas-Hoover melting point apparatus. Those above $240^{\circ} \mathrm{C}$ were measured on a Mel-Temp apparatus. All melting points are uncorrected. Infrared spectra were obtained on a Perkin-Elmer 297 grating spectrophotometer. Ultraviolet spectra were recorded on a Varian Cary 219 spectrophotometer. Mass spectroscopy was performed on an AE1 model MS-9 double-focusing spectrometer interfaced by Kratos Company to a Data General Nova 3. Regular mass spectra were recorded at 16 or 70 eV at the temperatures indicated. FABMS were conducted by using xenon ionization techniques at $25^{\circ} \mathrm{C}(6 \mathrm{kV}, 1 \mathrm{~mA})$ in a thioglycerol matrix. Proton NMR spectra were obtained at 200.1 MHz on a Bruker WP-200 spectrometer. Chemical shifts refer to tetramethylsilane as standard and $\mathrm{CHCl}_{3}$ at $\delta 7.24$ as reference. All elemental analyses were within $0.30 \%$ of theory unless otherwise listed.
2,2 $\mathbf{2}^{\prime}, \mathbf{2}^{\prime \prime}$-Trimethoxy-5,5', $\mathbf{5}^{\prime \prime}$-trimethyl[ $1,1^{\prime}: 3^{\prime}, 1^{\prime \prime}$-terphenyl]-3, $\mathbf{3}^{\prime \prime}$-dicarbonyl Dichloride (20). Diacid 19 ( $1.0 \mathrm{~g}, 2.2 \mathrm{mmol}$ ) was placed in a flask capped with a septum and flushed with argon. Thionyl chloride (1.6 $\mathrm{mL}, 22.2 \mathrm{mmol}$ ) which had been purified by distilling from triphenyl phosphite was added. The resulting mixture was stirred at $25^{\circ} \mathrm{C}$. The diacid was gradually dissolved. After $45 \mathrm{~min}, 30 \mathrm{~mL}$ of dry benzene was added to the paste, and the solution was evaporated to remove the excess thionyl chloride. This procedure was repeated twice. The product ( $97 \%$, 1.1 g ) was dried on the vacuum pump and used directly in the next reaction: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.37\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.42(\mathrm{~s}, 6 \mathrm{H}$, $\mathrm{ArCH}_{3}$ ), $3.20\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.57\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right), 7.18(\mathrm{~s}, 2 \mathrm{H}, \mathrm{ArH})$, $7.46\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=1.9 \mathrm{~Hz}, \mathrm{Ar} H\right), 7.83(\mathrm{~d}, 2 \mathrm{H}, J=1.9 \mathrm{~Hz}, \mathrm{Ar} H)$; IR $1770 \mathrm{~cm}^{-1}$.

1,7-Dioxa-4,10-diazacyclododecane (21). Phosphorus pentachloride ( $58 \mathrm{~g}, 0.28 \mathrm{~mol}$ ) was added to diglycolic acid ( $16 \mathrm{~g}, 0.12 \mathrm{~mol}$ ), and the mixture was dissolved in 200 mL of $\mathrm{CHCl}_{3}$. After stirring for 15 min at $25^{\circ} \mathrm{C}$, the solution was refluxed for 2 h , and the $\mathrm{POCl}_{3}$ and HCl were evaporated. The residue was fractionally distilled at $0.1-0.4 \mathrm{mmHg}$, and the 2,2-oxybis(acetyl chloride) was collected between $39-42^{\circ} \mathrm{C}$, the bath temperature being maintained below $80^{\circ} \mathrm{C}$. The product $[13.1 \mathrm{~g}(64 \%)$; ${ }^{1} \mathrm{H}$ NMR $\delta 4.57$ ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{CH}_{2}$ )] was used to react directly with 1,5 -di-amino-3-oxapentane, which was prepared as follows. Ammonia gas was bubbled for 30 min through a vigorously stirred suspension of $2,2-$ oxybis(ethylamine) dihydrochloride ( $3.0 \mathrm{~g}, 17 \mathrm{mmol}$ ) in 50 mL of $\mathrm{CHCl}_{3}-10 \% \mathrm{CH}_{3} \mathrm{OH}$ (v). The suspension dissolved and was replaced by a white precipitate, which was collected. The solvent of the filtrate was evaporated under reduced pressure to give the diamine, which was distilled at $8 \mathrm{mmHg}\left[\mathrm{bp} 42-44^{\circ} \mathrm{C} ; 1.7 \mathrm{~g}(94 \%) ;{ }^{1} \mathrm{H}\right.$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 1.40$ $\left(\mathrm{s}, 4 \mathrm{H}, \mathrm{N} H_{2}\right), 2.87\left(\mathrm{t}, 4 \mathrm{H}, J=5.1 \mathrm{~Hz}, C_{2} \mathrm{~N}\right), 3.49(\mathrm{t}, 4 \mathrm{H}, J=5.1$ $\mathrm{Hz}, \mathrm{CH}_{2} \mathrm{O}$ )]. This diamine ( $3 \mathrm{~g}, 26.3 \mathrm{mmol}$ ) in 50 mL of anhydrous benzene and 2,2-oxybis(acetyl chloride) ( $2.45 \mathrm{~g}, 13.2 \mathrm{mmol}$ ) in 50 mL of anhydrous benzene were placed in separate gas-tight syringes and added via a syringe pump to a 2-L Morton flask containing 1 L of violently stirred anhydrous benzene ( $25^{\circ} \mathrm{C}, 20 \mathrm{~min}$ ). The precipitate was collected and washed with hot $\mathrm{CHCl}_{3}$, and the filtrates were evaporated to give a residue which was recrystallized from $\mathrm{CHCl}_{3}$-heptane to produce $1.6 \mathrm{~g}(60 \%)$ of 5,9 -dioxo-1,7-dioxa-4,10-diazacyclododecane ( mp $169-173^{\circ} \mathrm{C}$ (lit. ${ }^{13} \mathrm{mp} 182-183^{\circ} \mathrm{C}$ ), ${ }^{1} \mathrm{H}$ NMR $\delta 3.47$ ( $\mathrm{t}, 4 \mathrm{H}, J=4.9$ $\mathrm{Hz}, \mathrm{CH}_{2} \mathrm{NH}$ ), $3.65\left(\mathrm{t}, 4 \mathrm{H}, \mathrm{J}=4.9 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{O}\right.$ ), $4.12\left(\mathrm{~s}, 4 \mathrm{H}, \mathrm{COCH}_{2} \mathrm{O}\right)$, 7.16 (brs, $2 \mathrm{H}, \mathrm{N} H$ )]. The diamine salt produced as the other product was recovered and recycled. The above lactam ( $2.0 \mathrm{~g}, 10 \mathrm{mmol}$ ) was
placed in a paper thimble of a Soxlet. A solution of $\mathrm{LiAlH}_{4}(2.0 \mathrm{~g})$ in 300 mL of freshly distilled THF (purity is important) was refluxed for 3 days to slowly dissolve the lactam and reduce it. The flask was cooled and stirred successively with 1.2 mL of $\mathrm{H}_{2} \mathrm{O}, 4 \mathrm{~mL}$ of pure THF (purity is important), 2.2 mL of $15 \%$ aqueous $\mathrm{NaOH}, 3.6 \mathrm{~mL}$ of $\mathrm{H}_{2} \mathrm{O}$, and 6 mL of pure THF. The white gelatinous precipitate was rinsed with 250 mL of pure THF. The combined organic layers were evaporated to give white crystals of 21 [ $1.60 \mathrm{~g}(93 \%), \mathrm{mp} 80-83^{\circ} \mathrm{C}$ (lit. ${ }^{13} 83-84^{\circ} \mathrm{C}$ ), ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{OCl}_{3}\right) \delta 2.16$ (brs, $2 \mathrm{H}, \mathrm{NH}$ ), $2.78-2.87\left(\mathrm{~m}, 8 \mathrm{H}, \mathrm{CH}_{2} \mathrm{~N}\right.$ ), 3.60-3.68(m, $\left.8 \mathrm{H}, \mathrm{CH}_{2} \mathrm{O}\right)$ ]

36,37,38-Trimethoxy-5,10,15-trimethyl-22,25,30,33-tetraoxa-1,19diazapentacyclo $\left[17.8 .8 .1^{3,7} \cdot 1^{13,17}\right]$ octatriaconta-3,5,7(38),8,10,12-(37),13,15,17(36)-nonaene-2,18-dione (16). Procedure A. Diacyl chloride $20(2.44 \mathrm{~g}, 5.01 \mathrm{mmol})$ was dissolved in 250 mL of anhydrous benzene and transferred in $50-\mathrm{mL}$ portions to a $50-\mathrm{mL}$ gas-tight syringe. Similarly, diamine $23(1.31 \mathrm{~g}, 5.01 \mathrm{mmol})$ together with triethylamine ( $1.52 \mathrm{~mL}, 10.9 \mathrm{mmol}$, distilled from tosyl chloride) in 150 mL of anhydrous benzene was transferred to a $50-\mathrm{mL}$ gas-tight syringe. These solutions were added ( 3 h ) via a syringe pump to an oven-dried 2-L Morton flask containing 1200 mL of vigorously stirred anhydrous benzene. The precipitated $\mathrm{Et}_{3} \mathrm{NHCl}$ was collected, the filtrate was evaporated, and the residue was purified by gel chromatography with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ as the mobile phase. Fractions of the main peak of retention volume of 132 mL were combined and evaporated to give 3.05 g ( $90 \%$ ) of 16 which was pure by ${ }^{1} \mathrm{H}$ NMR. A small sample was recrystallized from $\mathrm{CHCl}_{3}-\mathrm{CH}_{3} \mathrm{OH}$ for elemental analysis: $\mathrm{mp} 309-320{ }^{\circ} \mathrm{C}$ dec; ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.34$ (s, $6 \mathrm{H}, \mathrm{ArCH}_{3}$ ), 2.45 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}$ ), 2.71 ( s , $\left.3 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.37\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.07-3.50,3.60-3.95(\mathrm{~m}, 22 \mathrm{H}$, $\left.\mathrm{NCH}_{2}, \mathrm{OCH}_{2}\right), 4.29\left(\mathrm{~d}, 2 \mathrm{H}, \mathrm{J}=14.0 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{~N}\right), 7.08\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=\right.$ $0.5 \mathrm{~Hz}, \operatorname{Ar} H), 7.15\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=0.5 \mathrm{~Hz}, \mathrm{ArH}\right), 7.24(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar} H)$; IR $1625 \mathrm{~cm}^{-1} ; \mathrm{MS}\left(180^{\circ} \mathrm{C} 16 \mathrm{eV}\right), 676\left(\mathrm{M}^{+}, 85\right), 645\left(\mathrm{M}^{+}-\mathrm{OCH}_{3}, 100\right)$. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{48} \mathrm{~N}_{2} \mathrm{O}_{9}$ : C and H .

33,34,35-Trimethoxy-5,10,15-trimethyl-22,25,30-trioxa-1,19-diazapentacyclo[17.8.5.1 $\left.{ }^{3,7} .1^{13,17}\right]$ pentatriaconta-3,5,7(35),8,10,12-(34),13,15,17(33)-nonaene-2,18-dione ( 14 and 15). Diamine 22, a highly deliquescent compound, was quickly weighed ( $0.45 \mathrm{~g}, 2.06 \mathrm{mmol}$ ) and dried on the vacuum pump for 2 days. It was submitted to procedure A along with $\mathrm{Et}_{3} \mathrm{~N}(0.63 \mathrm{~mL}, 4.49 \mathrm{mmol})$ and $20(1.0 \mathrm{~g}, 2.06 \mathrm{mmol})$ with an addition time of 1 h . The fractions with a retention volume of 146 mL (gel permeation chromatography) produced $0.93 \mathrm{~g}(72 \%)$ of a mixture of isomers 14 and 15 pure to ${ }^{1} \mathrm{H}$ NMR [MS $\left(180^{\circ} \mathrm{C}, 16 \mathrm{eV}\right), 632$ $\left.\left(\mathrm{M}^{+}, 68\right), 601\left(\mathrm{M}^{+}-\mathrm{OCH}_{3}, 100\right)\right]$. The mixture of isomers pure to ${ }^{1} \mathrm{H}$ NMR, was separated by HPLC, 500 mg at a time, with two $500-\mathrm{g}$ columns connected in series with $\mathrm{CH}_{2} \mathrm{Cl}_{2}-1 \% \mathrm{CH}_{3} \mathrm{OH}$ (v) as the mobile phase with essentially base line separation in a $5: 2$ ratio. The major isomer 14 was crystallized from $\mathrm{CH}_{2} \mathrm{Cl}_{2}-\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CO}, \mathrm{mp} 337-345{ }^{\circ} \mathrm{C}$ dec; ${ }^{\text {t }} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.34\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.45\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right)$, $2.62\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.38\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right), 2.95-3.30,3.65-4.23(\mathrm{~m}, 18$ $\mathrm{H}, \mathrm{NCH}$ ) , $4.42\left(\mathrm{~d}, 2 \mathrm{H}, \mathrm{J}=15.2 \mathrm{~Hz}, \mathrm{NCH}_{2}\right), 7.11(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar} H), 7.13$ (s, $2 \mathrm{H}, \mathrm{Ar} H$ ), 7.25 (s, $2 \mathrm{H}, \mathrm{Ar} H$ ); IR $3000,1615 \mathrm{~cm}^{-1}$; UV $\left(\mathrm{CHCl}_{3}\right)$ $\lambda_{\max } 284 \mathrm{~nm}, \epsilon 7355$. Hexahydro\{ $\mathbf{( 3 6 , 3 7 , 3 8 - t r i m e t h o x y - 5 , 1 0 , 1 5 - t r i m e t h y l - 2 2 , 2 5 , 3 0 , 3 3 - t e t r a - ~}$ oxa-1,19-diazapentacyclo[17.8.8.1 $\left.{ }^{3,7} .1^{8,12} .1^{13,17}\right]$ octatriaconta-3,5,7-(38),8,10,12(37),13,15,17(36)-monaene- $\boldsymbol{N}^{1}: \boldsymbol{N}^{19}$ ) \}diboron (12). Procedure B. Lactam $16(0.24 \mathrm{~g}, 0.35 \mathrm{mmol})$ was dissolved in 40 mL of anhydrous THF and heated. When the solvent started to boil, borane methyl sulfide ( 9.9 mmol ) was added, and the methyl sulfide was slowly distilled away.

The reaction was followed by TLC. After about 50 min all the starting material had reacted, and TLC showed a main spot near the solvent front ( $10 \% \mathrm{CH}_{3} \mathrm{OH}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (v)) and a very faint spot at the origin. The flask was cooled to $25^{\circ} \mathrm{C}$, and the solvent was evaporated. The residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and cold water was added cautiously to destroy the remaining borane reagent. The solution was stirred for 15 min , and the layers were separated. The organic phase was washed with water and filtered through anhydrous calcium sulfate. The solvent was evaporated, and the residue was purified by filtration through 15 g of regular silica gel in a coarse fritted funnel. Product 12 was eluted with $10 \% \mathrm{CH}_{3} \mathrm{OH}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (v) and recrystallized from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ to give $0.107 \mathrm{~g}(87 \%), \mathrm{mp}$ with dec above $189^{\circ} \mathrm{C}:{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.36\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.45$ ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{ArCH}$ ), $2.78\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right.$ ), $3.37\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right), 2.50-4.16$ (m, $24 \mathrm{H}, \mathrm{NCH}_{2}, \mathrm{OCH}_{2}$ ), $3.66\left(\mathrm{~d}, 2 \mathrm{H}, J=12.5 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 4.61$ (d, $2 \mathrm{H}, J=12.5 \mathrm{~Hz}, \operatorname{ArCH}_{2} \mathrm{~N}$ ) , $7.16\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=1.7 \mathrm{~Hz}, \operatorname{Ar} H\right), 7.24$ ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{Ar} H), 7.31\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=1.7 \mathrm{~Hz}, \mathrm{Ar} H\right) ; \mathrm{MS}\left(280^{\circ} \mathrm{C}, 70 \mathrm{eV}\right)$, $648\left(\mathrm{M}^{+}-\left(\mathrm{BH}_{3}\right)_{2}, 2\right), 617\left(\mathrm{M}^{+}-\left(\mathrm{BH}_{3}\right)_{2} \mathrm{OCH}_{3}, 100\right)$. Hexahydro $(\mathbf{3 3}, 34,35-$ trimethoxy-5,10,15-trimethyl-22,25,30-trioxa-1,19-diazapentacyclo[17.8.5.1 $1^{3,7} .1^{8,12} .1^{13,17}$ ]pentatriaconta-3,5,7-(35),8,10,12(34),13,15,17(33)-nonaene- $\left.\left.\boldsymbol{N}^{1}: \boldsymbol{N}^{19}\right)\right\}$ diboron (11). Procedure C. Lactam $15\left(28.5 \mathrm{mg}, 4.5 \times 10^{-2} \mathrm{mmol}\right)$ was dissolved in 12 mL of anhydrous THF. A THF solution of $\mathrm{LiBH}_{4}(2 \mathrm{M}, 2.7 \mathrm{~mL})$ was added to the flask, and the mixture was stirred for 5 min . The flask was cooled to $-78^{\circ} \mathrm{C}$, and $700 \mu \mathrm{~L}$ of boron trifluoride etherate (distilled from $\mathrm{CaH}_{2}$ under reduced pressure) was added slowly. After the addition was completed, the solution was stirred for another 5 min before the cold bath was removed. The flask was allowed to warm to $25^{\circ} \mathrm{C}$. The reaction was followed by TLC and usually took 4-6 h. After 4.5 h , the flask was reimmersed in the cold bath, and water was added very cautiously to quench the remaining borane reagent. Methylene chloride and cold water were added, and the mixture was stirred for 10 min . The organic phase was washed once with water, dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, and evaporated under vacuum. The residue was chromatographed on a $0.5-\mathrm{mm}$ preparative TLC plate, and product was eluted with $2.5 \% \mathrm{CH}_{3} \mathrm{OH}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (v). The less polar band ( $R_{f} 0.62$ ) corresponded to the diborane complex of the major isomer 10 . The more polar band ( $R_{f} 0.53$ ) corresponded to the diborane complex of 11. About 20 mg of the mixture was obtained (69\%). The ratio of the major to the minor isomers was $1: 5 ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right)$ ) $2.34\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.47\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.60(\mathrm{~s}, 3 \mathrm{H}$, $\left.\mathrm{OCH}_{3}\right), 3.33\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right), 2.50-4.39(\mathrm{~m}, 20 \mathrm{H}, \mathrm{NCH}$ ), $3.60(\mathrm{~d}, 2$ $\mathrm{H}, J=13.9 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}$ ), $4.50\left(\mathrm{~d}, 2 \mathrm{H}, J=13.9 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 6.99$ (d, $2 \mathrm{H}, J_{m}=1.7 \mathrm{~Hz}, \operatorname{Ar} H$ ), $7.17\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=1.7 \mathrm{~Hz}, \mathrm{Ar} H\right), 7.29(\mathrm{~s}$, $2 \mathrm{H}, \mathrm{Ar} H)$. 25,26,27-Trimethoxy-4,9,23-trimethyl-16-oxa-13,19-diazatetracyclo[19.3.1.1 ${ }^{2,6} .1^{7,11}$ heptacosa-1 (25), 2,4,6(27), 7,9,11(26),21,23-nonaene (17). Lactam 18 ( $0.14 \mathrm{~g}, 0.27 \mathrm{mmol}$ ) was dissolved in 30 mL of anhydrous THF. A fourfold excess of $1 \mathrm{M} \mathrm{LiAlH}_{4}$ solution in THF (Aldrich 1.1 mL ) was added to the solution which was then heated to reflux. After 12 h, TLC indicated that all the starting material had reacted. The mixture was cooled to $25^{\circ} \mathrm{C}$, and the excess reagent was destroyed by adding $170 \mu \mathrm{~L}$ of 1 N aqueous NaOH . A precipitate formed which was filtered. The precipitate was rinsed with 2 portions of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and 2 portions of $\mathrm{CH}_{3} \mathrm{OH}$. The combined organic fractions were evaporated and the residue was partitioned between $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and aqueous $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{~N}$ OH . The organic layer was washed 3 times with the aqueous basic solution, and the organic solution was filtered through a piece of phase-separator filter paper. The solvent was evaporated to give a white foam, $110 \mathrm{mg}(85 \%)$ : ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.30(\mathrm{~s}, 6 \mathrm{H}, \mathrm{ArCH} 3), 2.46$ $\left(\mathrm{s}, 6 \mathrm{H}, \mathrm{ArCH} 3, \mathrm{OCH}_{3}\right), 3.38\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right), 2.36-3.66\left(\mathrm{~m}, 8 \mathrm{H}, \mathrm{NCH}_{2}\right.$, $\mathrm{OCH}_{2}$ ), $3.31\left(\mathrm{~d}, 2 \mathrm{H}, J=13.7 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 4.24(\mathrm{~d}, 2 \mathrm{H}, J=13.7$ $\left.\mathrm{Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 6.95\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=2.0 \mathrm{~Hz}, \mathrm{Ar} H\right), 7.01\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=2.0\right.$ $\mathrm{Hz}, \mathrm{Ar} H), 7.26(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar} H)$.

The sodium picrate complex $17 \cdot \mathrm{NaPic}$, was prepared by adding the salt as a solid to a solution of $\mathbf{1 7}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. After having been stirred for several hours, the solution was filtered from the excess salt, and the filtrate was evaporated to give 17. NaPic: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.34(\mathrm{~s}$ $6 \mathrm{H}, \mathrm{ArCH} 3), 2.50\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{ArCH}_{3}, \mathrm{OCH}_{3}\right), 3.44\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right)$, $2.32-3.67\left(\mathrm{~m}, 8 \mathrm{H}, \mathrm{NCH}_{2}, \mathrm{OCH}_{2}\right), 3.29\left(\mathrm{~d}, 2 \mathrm{H}, \mathrm{J}=12.2 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right)$, $4.30(\mathrm{~d}, 2 \mathrm{H}, J=12.2 \mathrm{~Hz}, \mathrm{ArCH} \mathrm{N}), 6.96\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=2.0 \mathrm{~Hz}, \operatorname{ArH}\right)$, $7.10\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=2.0 \mathrm{~Hz}, \operatorname{Ar} H\right), 7.32(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar} H), 8.85(\mathrm{~s}, 2 \mathrm{H}, \mathrm{ArH}$, picrate; FABMS (xenon ionization, $25^{\circ} \mathrm{C}$ ), $513\left(\mathrm{M}+\mathrm{Na}^{+}, 100\right)$

36,37,38-Trimethoxy-5,10,15-trimethyl-22,25,30,33-tetraoxa-1,19 diazapentacyclo[17.8.8. $1^{3,7} \cdot 1^{8,12} \cdot 1^{13,17}$ octatriaconta-3,5,7(36)-nonaene (8). Procedure D. Hydroborane complex $12(40 \mathrm{mg}, 0.059 \mathrm{mmol})$ was dissolved in 3 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and 1.5 mL of an aqueous 0.7 M Mg $(\mathrm{OAc})_{2} / \mathrm{AcOH}$ buffer was added. Equivalents (6) of iodine ( $90 \mathrm{mg}, 0.35$ mmol ) dissolved in 1 mL of THF was added dropwise (fiarly rapidly) to the solution. After having been stirred for 5 min at $25^{\circ} \mathrm{C}$, the layers were separated. The aqueous phase was washed with 1 portion of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and the organic portions were combined. The organic phase was washed with 2 portions of dionized water and shaken for a few min at a time with 2 portions of aqueous (deionized water) $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{NOH}$ or until the organic phase was colorless. The solution was filtered through a piece of phase-separator filter paper. The solvent was evaporated, and the white foam ( $30 \mathrm{mg}, 78 \%$ ) was dried on the vacuum pump: 'H NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.31(\mathrm{~s}, 6 \mathrm{H}, \mathrm{ArCH} 3$ ) $2.41(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH} 3), 2.83(\mathrm{~s}, 3 \mathrm{H}$ $\left.\mathrm{OCH}_{3}\right), 3.55\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right), 2.63-3.80\left(\mathrm{~m}, 24 \mathrm{H}, \mathrm{NCH}_{2}, \mathrm{OCH}_{2}\right), 3.04$ (d, $2 \mathrm{H}, J=11.8 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}$ ), $4.12\left(\mathrm{~d}, 2 \mathrm{H}, J=11.8 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right.$ ), $6.95\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=1.9 \mathrm{~Hz}, \mathrm{Ar} H\right), 7.03\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=1.9 \mathrm{~Hz} \mathrm{ArH}\right), 7.16$ (s, $2 \mathrm{H}, \mathrm{ArH}) ; \mathrm{MS}\left(320^{\circ} \mathrm{C}, 70 \mathrm{eV}\right), 648\left(\mathrm{M}^{+}, 2\right) 617\left(\mathrm{M}^{+}-\mathrm{OCH}_{3}\right.$, 100). Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{52} \mathrm{~N}_{2} \mathrm{O}_{7} \mathrm{NH}_{4} \mathrm{C}_{8} \mathrm{H}_{2} \mathrm{~N}_{3} \mathrm{O}_{7}$ : C, 59.05; H, 6.53. Found: C, 58.87; H, 6.57 .

33,34,35-Trimethoxy-5,10,15-trimethyl-22,25,30-trioxa-1,19-diazapentacyclo $\left[17.8 .5 .1^{3.7} .1^{8,12} .1^{13,17}\right]$ pentatriaconta-3,5,7(35),8,10,12-(34),13,15,17(33)-nonaene (6). Hydroborane complex 10 ( $29 \mathrm{mg}, 0.046$ mmol ) was dissolved in 5 mL of THF. Hydrochloric acid ( $1 \mathrm{M}, 92 \mu \mathrm{~L}$ ) was added to this solution which was heated to reflux. The reaction was follwed by TLC. After 30 min , all the starting material had reacted. The mixture was cooled to $25^{\circ} \mathrm{C}$, and the solvent was evaporated. The residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and the solution was washed twice with $3 \mathrm{~N}\left(\mathrm{CH}_{3}\right)_{4} \mathrm{NOH}$. It was then stirred with aqueous sodium picrate containing a small amount of $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{NOH}$. The layers were separated, and the organic phase was filtered through a piece of phase-separator filter paper. The solvent was evaporated, and the residue was chromatographed on a $1-\mathrm{mm}$ preparative TLC plate with a $20 \% \mathrm{EtOH} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$ (v) eluting solvent. The sodium picrate complex of 6 was obtained ( 22 $\mathrm{mg}, 56 \%$ ). The lithium picrate complex of 6 was obtained by stirring a methanol solution of the sodium complex with a huge excess of ultra-pure LiCl (Alfa-Ventron) for 24 h . The methanol was evaporated, and the residue was partitioned between $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and water. The organic phase was washed with 2 more portions of water and then filtered through a piece of phase-separator filter paper. The solvent was evaporated to give the lithium picrate complex of 6 . The potassium picrate complex was obtained in a similar manner by stirring with potassium picrate in methanol.

Compound 6 was also obtained from the hydroborane complex 11, the minor isomer. Complex $11(20 \mathrm{mg}, 0.032 \mathrm{mmol})$ was submitted to procedure D ( 48 mg of $\mathrm{I}_{2}$ was used). The final $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution of 6 and 7 was stirred with an aqueous solution of NaPic containing a trace of $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{NOH}$ for 0.5 h . The organic phase was filtered through phaseseparator filter paper. The solvent was evaporated, and the residue was chromatographed on a $1-\mathrm{mm}$ preparative TLC plate with $20 \% \mathrm{EtOH}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ as the mobile phase. The complex $6 \cdot \mathrm{NaPic}$ was obtained ( 17 mg , $62 \%$ ). These complexes of 6 were characterized as follows. Complex 6.LiPic: ${ }^{\text {' }} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.36\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.49(\mathrm{~s}, 3 \mathrm{H}$, $\left.\mathrm{ArCH}_{3}\right) 2.57\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.43\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right), 2.33-4.00(\mathrm{~m}, 20 \mathrm{H}$, $\left.\mathrm{NCH}_{2}, \mathrm{OCH}_{2}\right), 2.93(\mathrm{~d}, 2 \mathrm{H}, J=12.2 \mathrm{~Hz}, \mathrm{ArCH} 2 \mathrm{~N}), 4.41(\mathrm{~d}, 2 \mathrm{H}, J$ $\left.=12.2 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 7.01\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=2.0 \mathrm{~Hz}, \mathrm{Ar} H\right), 7.16(\mathrm{~d}, 2 \mathrm{H}$, $\left.J_{m}=2.0 \mathrm{~Hz}, \operatorname{Ar} H\right), 7.32(\mathrm{~s}, 2 \mathrm{H}, \operatorname{ArH}), 8.89(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar} H$, picrate $)$. Complex 6.NaPic: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.34\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.42(\mathrm{~s}$, $3 \mathrm{H}, \mathrm{ArCH} 3$ ), $2.49\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.36\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right), 1.88-4.24(\mathrm{~m}$, $\left.20 \mathrm{H}, \mathrm{NCH}_{2}, \mathrm{OCH}_{2}\right), 2.64\left(\mathrm{~d}, 2 \mathrm{H}, J=11.7 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 4.44(\mathrm{~d}, 2$ $\left.\mathrm{H}, J=11.7 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 6.97\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=2.0 \mathrm{~Hz}, \mathrm{Ar} H\right), 7.12(\mathrm{~d}$, $\left.2 \mathrm{H}, J_{m}=2.0 \mathrm{~Hz}, \mathrm{Ar} H\right), 7.32(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar} H), 8.81$ (s, $2 \mathrm{H}, \mathrm{Ar} H$, picrate); FABMS (xenon ionization, $25^{\circ} \mathrm{C}$ ), $627.39\left(\mathrm{M}+\mathrm{Na}^{+}, 18\right), 605.40(\mathrm{M}$ $+\mathrm{H}^{+}, 23$ ). Complex $6 \cdot \mathrm{KPic}:{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.23\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right)$, $2.30\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.49\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.48\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right)$, 1.88-4.14 (m, $22 \mathrm{H}, \mathrm{NCH}_{2}, \mathrm{OCH}_{2}, \mathrm{ArCH}_{2} \mathrm{~N}$ ), 4.33 (d, $2 \mathrm{H}, J=14.0$ $\left.\mathrm{Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 6.95\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=1.9 \mathrm{~Hz}, \mathrm{Ar} H\right), 7.02\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=1.9\right.$ $\mathrm{Hz}, \mathrm{Ar} H), 7.32(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar} H), 8.82$ (s, $2 \mathrm{H}, \mathrm{Ar} H$, picrate).

30,31,32-Trimethoxy-5,10,15-trimethyl-22,27-dioxa-1,19-diazapentacyclo[17.5.5.1 $\left.1^{3,7} .1^{8,12} .1^{13,17}\right]$ dotriaconta-3,5,7(32),8,10,12(31),13,15,17-(33)-nonaene (5). Hydroborane complex 9 ( $20 \mathrm{mg}, 0.034 \mathrm{mmol}$ ) and $52.8 \mathrm{mg}(0.2 \mathrm{mmol})$ of iodine were submitted to procedure D to give 5 as a thin film, which was dried under high vacuum to give 18 mg (94\%) of 5: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.30(\mathrm{~s}, 6 \mathrm{H}, \mathrm{ArCH} 3), 2.44\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH} \mathrm{H}_{3}\right)$, $2.58\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.30\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right), 2.28-4.08(\mathrm{~m}, 18 \mathrm{H}, \mathrm{NCH} 2$, $\mathrm{OCH}_{2}, \mathrm{ArCH}_{2} \mathrm{~N}$ ), $3.93\left(\mathrm{~d}, 2 \mathrm{H}, J=12.7 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 6.86(\mathrm{~d}, 2 \mathrm{H}$, $\left.J_{m}=1.5 \mathrm{~Hz}, \operatorname{Ar} H\right), 7.06\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=1.5 \mathrm{~Hz}, \operatorname{Ar} H\right), 7.23(\mathrm{~s}, 2 \mathrm{H}$, $\mathrm{ArH})$; FABMS (xenon ionization, $25^{\circ} \mathrm{C}$ ), $560\left(\mathrm{M}^{+}, 100\right), 546\left(\mathrm{M}^{+}\right.$$\left.\mathrm{CH}_{3}+\mathrm{H}, 7\right), 530\left(\mathrm{M}^{+}-\mathrm{OCH}_{3}+\mathrm{H}\right)$.

Compound 5 was characterized as its $\mathrm{NaB}(\mathrm{Ph})_{4}$ complex made by stirring 5 in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ with aqueous $\mathrm{NaB}(\mathrm{Ph})_{4}$ containing a trace of $(\mathrm{C}$ $\left.\mathrm{H}_{3}\right)_{4} \mathrm{NOH}$. The layers were separated, the organic phase was concentrated, and the $5 \cdot \mathrm{NaB}(\mathrm{Ph})_{4}$ was crystallized by adding $\mathrm{CH}_{3} \mathrm{OH}$ : ${ }^{\text {' }} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.38$ ( $\mathrm{s}, 6 \mathrm{H}, \mathrm{ArCH}_{3}$ ), 2.43 (s, $3 \mathrm{H}, \mathrm{ArCH}_{3}$ ), 2.51 (s, $\left.3 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.33\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{OCH}_{3}\right), 1.94-3.60\left(\mathrm{~m}, 16 \mathrm{H}, \mathrm{NCH}, \mathrm{OCH}_{2}\right)$, $2.99\left(\mathrm{~d}, 2 \mathrm{H}, J=12.0 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 3.97(\mathrm{~d}, 2 \mathrm{H}, J=12.0 \mathrm{~Hz}$, $\mathrm{ArCH}_{2} \mathrm{~N}$ ), 6.84-7.48 (m, $26 \mathrm{H}, \mathrm{ArH}$ ). Anal. Caled for $\mathrm{C}_{34} \mathrm{H}_{44} \mathrm{~N}_{2} \mathrm{O}_{5}$. $\mathrm{NaB}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \cdot 0.8 \mathrm{CH}_{2} \mathrm{Cl}_{2}: \mathrm{C}, 72.74 ; \mathrm{H}, 6.81$. Found: $\mathrm{C}, 72.58 ; \mathrm{H}, 7.14$. The crystal structure of $5 . \mathrm{NaB}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}$ contains $\mathrm{CH}_{2} \mathrm{Cl}_{2}$.

The diprotonated form of 5 gave the following ${ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta$ $2.36\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.48\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.49(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH} 3), 3.41$
(s, $6 \mathrm{H}, \mathrm{OCH}_{3}$ ), 2.23-4.40 (m, $16 \mathrm{H}, \mathrm{NCH}_{2}, \mathrm{OCH}_{2}$ ), $3.11(\mathrm{~d}, 2 \mathrm{H}, \mathrm{J}=$ $13.2 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}$ ), 4.09 (d, $2 \mathrm{H}, J=13.2 \mathrm{~Hz}, \mathrm{ArCH} 2 \mathrm{~N}$ ), 7.00 (d, 2 H , $\left.J_{m}=1.5 \mathrm{~Hz}, \operatorname{Ar} H\right), 7.15\left(\mathrm{~d}, 2 \mathrm{H}, J_{m}=1.5 \mathrm{~Hz}, \operatorname{Ar} H\right), 7.34(\mathrm{~s}, 2 \mathrm{H}$, $\mathrm{Ar} H$ ).

What is probably $5 . \mathrm{I}^{+} \mathrm{I}^{-}$gave the following: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.35$ $(\mathrm{s}, 6 \mathrm{H}, \mathrm{ArCH} 3), 2.46\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{ArCH}_{3}\right), 2.62\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.31(\mathrm{~s}$, $\left.6 \mathrm{H}, \mathrm{OCH}_{3}\right), 2.96-3.87\left(\mathrm{~m}, 16 \mathrm{H}, \mathrm{NCH}_{2}, \mathrm{OCH}_{2}\right), 4.22(\mathrm{~d}, 2 \mathrm{H}, J=13.2$ $\left.\mathrm{Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 4.34\left(\mathrm{~d}, 2 \mathrm{H}, J=13.2 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{~N}\right), 7.15(\mathrm{~d}, 2 \mathrm{H}$, $\operatorname{Ar} H), 7.19(\mathrm{~d}, 2 \mathrm{H}, \mathrm{Ar} H), 7.26$ (s, $2 \mathrm{H}, \mathrm{Ar} H$ ); FABMS (xenon ionization, $\left.0^{\circ} \mathrm{C}\right), 687\left(\mathrm{M}+\mathrm{I}^{+}, 0.6\right), 561\left(\mathrm{M}+\mathrm{H}^{+}, 100\right), 583\left(\mathrm{M}+\mathrm{Na}^{+}, 21\right)$.

Crystal Structures. Compounds $5 \cdot \mathrm{Na}^{+}, 8 \cdot \mathrm{Na}^{+}, 8 \cdot \mathrm{~K}^{+}, 8 \cdot \mathrm{Cs}^{+}$, and 9 are crystallized in the monoclinic system in space groups $P 2_{1} / n, C c, P 2_{1} / c$, $P 2_{1} / c$ and $P 2_{1} / m$, respectively. Unit cell dimensions are as follows: 5. $\mathrm{Na}^{+} a=19.919$ (2) $\AA, b=14.725$ (2) $\AA, c=21.387$ (2) $\AA, \beta=111.85$ (3) ${ }^{\circ}, Z$ (the number of molecules in the unit cell) $=4 ; 8 \cdot \mathrm{Na}^{+} a=16.907$ (6) $\AA \hat{A}, b=12.543$ (4) $\AA, c=20.860$ (7) $\AA, \beta=117.89$ (3) ${ }^{\circ}, Z=4$; 8. $\mathrm{K}^{+}$ $a=14.078$ (4) $\AA, b=11.367$ (3) $\AA, c=25.909$ (7) $\AA, \beta=101.48(2)^{\circ}$, $Z=4 ; 8 . \mathrm{Cs}^{+} a=11.329$ (3) $\AA, b=14.364$ (5) $\AA, c=26.219$ (10) $\AA$, $\beta=105.03(3)^{\circ}, Z=4 ; 9 a=15.605(11) \AA, b=15.799$ (7) $\AA, c=$
15.023 (7) $\AA, \beta=94.43(5)^{\circ}, Z=4$ (two crystallographically unrelated molecules each having a mirror plane through the molecule are found in this unit cell). Compounds $6 \cdot \mathrm{~K}^{+}, 14$, and 15 crystallize in the orthorhombic system in space groups Pnma, $P 2_{1} n a$ and Pnma, respectively. Unit cell dimensions are as follows: $\mathbf{6} \cdot \mathrm{K}^{+} a=21.210$ (9) $\AA, b=14.745$ (6) $\AA, c=11.808$ (5) $\AA, Z=4$ (the molecule contains a crystallographic mirror plane); $14 a=11.318$ (3) $\AA, b=7.835$ (1) $\AA, c=37.230$ (8) $\AA$, $Z=4 ; 15 a=16.056$ (4) $\AA, b=15.370$ (4) $\AA, c=14.640$ (3) $\AA, Z=$ 4 (the molecule contains a crystallographic mirror plane). With the exception of $6 \cdot \mathrm{~K}^{+}$and $5 \cdot \mathrm{Na}^{+}$, which were examined on a modified Picker FACS1 diffractometer, all measurements were taken on a Syntex PI diffractometer. All measurements except for those of 15 , which involved $\mathrm{Cu} \mathrm{K} \alpha$ radiation, made use of Mo $\mathrm{K} \alpha$ radiation. Measurements were made at ambient temperature except for 9 and 14, which were made at 115 K . Refinement of the eight structures gave $R$ values currently at $5 \cdot \mathrm{Na}^{+} 0.16,6 \cdot \mathrm{~K}^{+} 0.08,8 \cdot \mathrm{Na}^{+} 0.06,8 \cdot \mathrm{~K}^{+} 0.14,8 \cdot \mathrm{Cs}^{+} 0.08,90.08,14$ 0.08 , and 150.08 . All but $8 . \mathrm{Cs}^{+}$, which was solved by using heavy atom methods, were solved by using direct methods. Full details will be published elsewhere.

# Host-Guest Complexation. 39. Cryptahemispherands Are Highly Selective and Strongly Binding Hosts for Alkali Metal Ions ${ }^{1}$ 

Donald J. Cram* and Siew Peng Ho<br>Contribution from the Department of Chemistry and Biochemistry, University of California, Los Angeles, California 90024. Received October 15, 1985

#### Abstract

The association constants ( $K_{\mathrm{a}}, \mathrm{M}^{-1}$ ) and free energies of binding ( $-\Delta G^{\circ}$, $\mathrm{kcal} \mathrm{mol}^{-1}$ ) have been measured at 25 ${ }^{\circ} \mathrm{C}$ in $\mathrm{CDCl}_{3}$ saturated with $\mathrm{D}_{2} \mathrm{O}$ for cryptahemispherands $1-3$, cryptands $9-11$, and diazahemispherand 4 binding the alkali metal picrate salts. Methods were used in which complexes whose $K_{\mathrm{a}}$ values had been determined were equilibrated with hosts of unknown values. The equilibrium points were determined by ${ }^{1} \mathrm{H}$ NMR spectral methods. The cryptahemispherands as a class were found to be more powerful complexing agents than the cryptands. The two classes exhibited comparable ion selectivities. Plots of the $-\Delta G^{\circ}$ values of the cryptands in $\mathrm{CDCl}_{3}-\mathrm{D}_{2} \mathrm{O}$ vs. those in $95 \% \mathrm{CH}_{3} \mathrm{OH}-5 \% \mathrm{H}_{2} \mathrm{O}$ were linear. The $-\Delta G^{\circ}$ values for eight different sets of binding partners in $\mathrm{CDCl}_{3}-\mathrm{D}_{2} \mathrm{O}$ were found to be $5.2 \pm 0.4 \mathrm{kcal} \mathrm{mol}^{-1}$ higher than the corresponding eight values in $\mathrm{CH}_{3} \mathrm{OH}-\mathrm{H}_{2} \mathrm{O}$. The results are discussed in terms of the relative states of preorganization for binding and desolvation of the various host classes.

The previous paper in this series reports the syntheses and crystal structures of complexes whose hosts belong to a new subclass called the cryptahemispherands, whose bicyclic structures are illustrated by $1-3$. The monocyclic diazahemispherand 4 was also prepared for purposes of comparison. ${ }^{2}$ Hosts 1-3 combine certain structural features of the spherands (5-7), ${ }^{3,4}$ the hemispherands (e.g., 8), ${ }^{5}$ and the cryptands (9-11), ${ }^{6-8}$ which in turn are relatives of the chorands (e.g., 12). ${ }^{9}$ The trisanisyl molecular modules of 1-8 and the tetraanisyl module of reference compound $13{ }^{10}$ are organized for binding during their syntheses rather than

[^6]during the act of complexation. In these modules, the unshared electron pairs of the oxygens face inward toward the cavity, and their attached methyl groups are oriented outward, shielding the oxygens from solvation. In contrast, the $\left(\mathrm{CH}_{2} \mathrm{OCH}_{2}\right)_{m}$ and $\left(\mathrm{CH}_{2}\right)_{3} \mathrm{~N}$ modules of 1-4 and 8-12 are conformationally mobile. The unshared electron pairs of their heteroatoms can face outward to be solvated or inward toward solvent parts occupying the cavity. The methylene groups can turn inward to fill the cavity or outward when the cavity is filled. Upon complexation with cations, the guest must conformationally reorganize these chains and displace solvent bound to their heteroatoms in the process. ${ }^{3}$ The chorands, and particularly the cryptands, are preorganized for binding with respect to the sequences of their atoms but not with regard to their conformations or competitive complexation with solvent. The spherands are preorganized with respect to their atomic sequences, their conformations, and the unsolvated states of their heteroatoms.

This paper reports the association constants and free energies of complexation of alkali metal and ammonium picrates by cryptahemispherands $1-3$, diazahemispherand 4 , and cryptands $9-11$ at $25^{\circ} \mathrm{C}$ in $\mathrm{CDCl}_{3}$ saturated with $\mathrm{D}_{2} \mathrm{O}$. The values obtained are compared with those reported for the spherands in the same
