Complexation and Exchange Reactions of some Dimethylamino-substituted Group 4 Compounds

By Steven R. Wade and Gerald R. Willey,* Department of Chemistry and Molecular Sciences, University of Warwick, Coventry CV4 7AL

Reactions of $CH_2(NMe_2)_2$, (1), $SiMe_2(NMe_2)_2$, (2), $[Ti(cp)(NMe_2)_3]$ ($cp = \eta$ -cyclopentadienyl), (3), and $[Zr(cp)_2(NMe_2)_2]$, (4), with covalent metal halides MCl_4 (M = Ti, Zr, Hf, Si, Ge, or Sn) and MCl_3 (M = Ti, V, or Cr) fall into two categories: (a) N-donor chelation leading to complex formation and (b) halide-NMe₂ exchange. Compound (1) gives 1 : 1 complexes with MCl_4 (M = Ti or Sn) and a 2 : 1 complex with VCl_3 . Compound (2) provides 1 : 1 complexes with MCl_4 (M = Ti, Zr, Hf, or Sn). The decomposition of $TiCl_4$ ·SiMe₂(NMe₂)₂ \longrightarrow [TiCl_3(NMe₂)] invariably occurs in both the solid state and solution. There is no reaction of (2) with metal(III) chlorides. With MCl_4 (M = Si or Ge) ' scrambling ' reactions of (3) and (4) with MCl_4 (M = Si, Ge, Sn, Ti, Zr, or Hf) consistently feature halide-NMe₂ exchange rather than adduct formation. All complexes have been characterised by analytical and spectroscopic (¹H n.m.r. and i.r.) investigations.

AMIDES of Group 4 with a direct M-NR₂ linkage exhibit a wide range of chemical behaviour. Characteristically they are poor Lewis bases. Loss of electron density at nitrogen through internal p_{π} - d_{π} bonding weakens their donor capacity compared with the carbon analogues as demonstrated by various spectroscopic¹ and calorimetric² data. Facile bond cleavage of the metal-nitrogen bond with *e.g.* protic reagents ³⁻⁵ and the many exchange reactions involving group redistribution or 'scrambling' with metal or metalloidal halides ⁶⁻⁸ add a further complication by severely restricting the choice of reference Lewis acid.

Early co-ordination studies with dimethylaminosubstituted silanes provided several 1:1 complexes with the soft Lewis acids B_2H_6 and MMe_3 (M = B, Al, or Ga); in general these were found to be thermally unstable with complete decomposition at room temperature.^{9,10} Adduct formation between $SiMe_x(NMe_2)_{4-x}$ (x = 1 or 2) and the hard acids MCl_4 (M = Sn, Ti, or Zr) and $VOCl_3$ is reported, although detailed characterisation is lacking.¹¹ Cyclic silicon amines $(Me_2Si-NH)_x$ (x = 3 or 4) give a series of 1:1 and 1:2 complexes with TiCl₄ and MCl₃ (M = Ti, V, or Cr).¹² The chelate ligands L, Me₂XM'- $Me_2CH_2X'Me_2$ (X,X' = N, P, or As; M' = Si or Ge), provide a range of $[M(CO)_4L]$ complexes (M = Cr, Mo,or W) involving X, X' co-ordination to the metal.¹³ The compounds $M(NMe_2)_4$ (M = Sn or Ti) form 1:1 complexes with SnCl₄ but details are scant.¹¹ Reaction of $Sn(NR_2)_2$ with an excess of BF₃ gives the recently reported $Sn(NR_2)_2$ ·3BF₃.¹⁴ Perhaps the best characterised Group 4A amide complexes involve the monomeric $[M(CO)_{3}{Ti(cp)(NMe_{2})_{3}}]$ (M = Cr, Mo, or W) (cp = η cyclopentadienyl) in which the titanium amide acts as a terdentate N-donor.¹⁵ Herein we report our studies of the chelate co-ordination behaviour of a selection of dimethylamino-substituted compounds of Groups 4A and 4B.

EXPERIMENTAL

Solvents were distilled under nitrogen from either CaH_2 or P_2O_5 prior to use. Anhydrous metal chlorides and $CH_2(NMe_2)_2$, (1), were used as supplied commercially. $SiMe_2(NMe_2)_2$, (2), was obtained from direct dimethylaminolysis of $SiMe_2Cl_2$ in n-hexane. $[Ti(cp)(NMe_2)_3]$, (3), was isolated as a deep red semi-crystalline solid (36% yield) from lithioaminolysis of $[Ti(cp)_2Cl_2]$ in n-hexane-toluene. The 'expected ' product of the reaction, $[Ti(cp)_2(NMe_2)_2]$, obtained by Chandra and Lappert ⁴ via the same route under similar reaction conditions was not detected. $[Zr-(cp)_2(NMe_2)_2]$, (4), was prepared by the literature method.⁴

Infrared spectra were recorded on a Perkin-Elmer 580B spectrophotometer with samples as Nujol and hydrocarbon mulls sandwiched between CsI plates. Hydrogen-1 n.m.r. spectra were obtained using a Perkin-Elmer R34 (220-MHz) spectrometer with C_6D_6 or CD_3NO_2 solutions (SiMe₄ as internal standard).

Complexes were prepared under an inert atmosphere of nitrogen by dropwise addition of benzene solutions of the appropriate metal halide to a solution of the ligand, also in benzene. In a typical reaction SnCl_4 (1 cm³, 8.5 mmol) was slowly added to $\text{SiMe}_2(\text{NMe}_2)_2$ (1.5 cm³, 8.5 mmol) to give an immediate white precipitate of $\text{SnCl}_4 \cdot \text{SiMe}_2(\text{NMe}_2)_2$. The product was collected, washed with benzene and n-hexane, and purified by vacuum sublimation (3.1 g, 91%). Satisfactory microanalyses were obtained for all complexes.

RESULTS AND DISCUSSION

 $CH_2(NMe_2)_2$, (1).—Dropwise addition of (1) to equimolar amounts of MCl₄ (M = Ti or Sn) in benzene provided the yellow (M = Ti) and white (M = Sn) 1 : 1 adducts in almost quantitative yield. No further reaction occurs with an excess of ligand. The complexes, which are extremely sensitive to hydrolysis, show limited solubility in organic solvents. Analytical and spectral data indicate a *cis*-octahed ral chelated structure (Figure 1). Ligand bands in the i.r. spectrum at 1 058 [v(NC₂)_{asym}] and 868 [v(NC₂)_{asym}] cm⁻¹ shift to lower energy: *e.g.*, for M = Ti, v(NC₂)_{asym} 1 041, 991, 952 cm⁻¹; v(NC₂)_{sym} 860, 813 cm⁻¹, while the distinctive 1 383 cm⁻¹ (CH₂ deformation) band ¹⁶ experiences a shift to higher energy (70-75 cm⁻¹) on complexation. Separate intense v(M-Cl) bands at 397, 379, 356, 332 (M = Ti) and 337, 319 (M = Sn) support the proposed *cis* formulation. A single NMe₂ signal δ 2.80 [(1), δ 2.10] in the ¹H n.m.r. spectrum (M = Sn) confirms equivalent N-donor sites. Previous investigation of the TiCl₄-(1) system resulted in a series of dark yellow to green complexes of varying composition ¹⁷ (suggestive of partial hydrolysis and/or reduction).

Reaction with VCl₃ gave an insoluble chocolate-brown solid approximating to VCl₃·0.5CH₂(NMe₂)₂. The 1:1 complex, isolated indirectly from the reduction of VCl₄ with $B_2(NMe_2)_4$, has been interpreted as a monomeric five-co-ordinate vanadium(III) species with bidentate (chelate) ligand attachment.¹⁶ Infrared spectral data for VCl₃·0.5CH₂(NMe₂)₂ indicate both unidentate (1 368, 1 063, 1 045 cm⁻¹) and bidentate (1 040, 1 024, 998, 974, 963 cm⁻¹) ligand attachment. The pattern of v(VCl)bands (387, 350, 315, 277 cm⁻¹) resembles that of the brown compound VCl_a·NMe_a and implies bridging halogen.¹⁸ Mixing of VCl₃·0.5CH₂(NMe₂)₂ with neat pyridine (py) gives total ligand replacement with formation of the mauve VCl₃·3py.¹⁹ As a direct comparison, the donor behaviour of the phosphorus analogue CH₂(PPh₂)₂ (dpm) with TiCl₄ was also investigated. Dropwise addition of dpm to an equimolar amount of TiCl₄ in benzene solution gave the bright orange 1:1 complex. Intense v(TiCl) bands at 388, 380, 345, and 320 cm⁻¹ support an expected cis-octahedral (C_{2v}) structure (Figure 1). Bands at 469 and 416 cm⁻¹ are assigned as v(Ti-P) stretching modes.²⁰ The ¹H n.m.r. spectrum shows the methylene protons at δ 3.73 [$J(^{31}P-^{1}H)$ 6.6 Hz] and the ring protons at δ 6.4—6.8 (complex multiplet). The observed increase in the P-H coupling constant $[J(^{31}P-^{1}H) 2.0 Hz]$ dpm] reflects the increased s character in the P-C bonds following P donation; the drastic change in the aromatic region profile, δ 7.41 (meta) and δ 7.21 (ortho and *para*) multiplets (dpm), could well suggest deviation from a planar TiP₂C configuration with non-equivalent phenyl groups. Chelation of dpm [and also the arsenic analogue CH₂(AsPh₂)₂] often results in significant displacement of the methylene group from the MP₂ plane.²¹

 $SiMe_2(NMe_2)_2$, (2).—Dropwise addition (273 K) of (2) to equimolar quantities of MX_4 (M = Zr, Hf, or Sn, X = Cl; M = Sn, X = Br) in benzene solution gave immediate precipitation of the appropriate 1:1 complexes. Increasing the ligand : metal ratio does not result in further complexation. The white solids were extremely air- and moisture-sensitive and showed a general insolubility in organic solvents. The one exception, SnCl₄· SiMe₂(NMe₂)₂, was somewhat soluble in benzene, CHCl₃, and CH₂Cl₂ and could be recrystallised in low yield from the latter; additionally, it sublimes *in vacuo* (403—410 K) without apparent change.

Under similar conditions, the reaction of (2) with $TiCl_4$ gave a pale yellow precipitate which on standing even at 273 K fairly rapidly turned to a green solid.

Subsequent work-up yielded dark green crystals of [TiCl₃(NMe₂)] and SiMe₂Cl(NMe₂), b.p. 380 K (760 mmHg*). We were able to successfully isolate pure samples of the yellow 1: 1 complex on changing to the less polar n-hexane as solvent (273 K). Inevitably contamination with [TiCl₃(NMe₂)] slowly sets in however, even with samples stored in glass ampoules under a nitrogen atmosphere (273 K). Repeating the reaction with a two-fold excess of (2) again gives SiMe₂Cl(NMe₂) as the sole silicon-containing product together with a chocolatebrown solid approximating to [TiCl₂(NMe₂)₂]. The ¹H n.m.r. spectrum shows a complicated pattern for N-CH₃ protons, including an intense broad resonance at δ 3.5, a paramagnetic titanium(III) species perhaps. Quite possibly this is identical with the non-stoicheiometric product noted by Bürger and Neese 22 from the reaction of TiCl₄ and SiMe₃(NMe₂). Pure [TiCl₂(NMe₂)₂] is reported as brown crystals from the disproportionation of $TiCl_4$ and $Ti(NMe_2)_4$.²³ The reaction between (2) and CrCl₃·2NMe₃ in benzene solution resulted in formation of the decomposition product Cr₂Cl₆(NMe₃)₃.²⁴ With VCl₃·3MeCN, ligand exchange occurred but the resulting mauve vanadium(III) species proved to be non-stoicheiometric.

A cis-octahedral (C_{2v}) structure (Figure 1) is proposed for the series MCl₄·SiMe₂(NMe₂)₂. The i.r. spectra of the complexes show a conspicuous similarity; the major variations from that of the free ligand occur in the 500-900 cm⁻¹ region, reflecting the change in Si-N bonding following complexation. Intense metal-halogen stretching bands were observed at 340, 328, 320, 260 cm⁻¹, v(SnCl); 417, 405, 365, 322 cm⁻¹, v(TiCl); 344, 311 cm⁻¹, v(ZrCl); and 342, 313 cm⁻¹ v(HfCl). SnBr₄. SiMe₂(NMe₂)₂ shows one broad and intense band at 210-220 cm⁻¹ v(SnBr). Proton n.m.r. data (δ) are limited (solubility) to $SnCl_4$ ·SiMe₂(NMe₂)₂ [0.36(6) (SiCH₃), 2.19(6), 2.17(6) (NCH₃)]; $SnBr_4 \cdot SiMe_2(NMe_2)_2$ [0.38(6) (SiCH₃), 2.14(6), 2.12(6) (NCH₃)]; and ZrCl₄·SiMe₂(NMe₂)₂ [0.37(6) (SiCH₃), 2.15(6), 2.09(6) (NCH₃)]. Uncomplexed ligand (2) shows singlets at $\delta 0.10(6)$ (SiCH₃) and 2.45(12) (NCH₂). Each complex shows a sharp doublet for the NMe, protons at room temperature; these are temperature dependent with decay to a broad singlet on increasing the temperature (373 K). For a five-co-ordinate metal geometry (Figure 2) the separate donor and dangling' NMe2 sites would account for the doublet. Raising the temperature would increase the exchange rate between free and bound sites, until in the fastexchange limit the two signals coalesce. Alternatively, a six-co-ordinate metal geometry (Figure 1) could give non-equivalent NMe_2 groups as a result of non-planarity of the equatorial MX₂SiN₂ plane. Rapid inversion of the chelate ring at higher temperature averages out the different sites causing collapse to a single resonance. On balance, the latter model is favoured, *i.e.* the likelihood that the solid-state structure persists in solution fits in with the known preference for six-co-ordination for M^{IV}.

Direct mixing of (2) and MCl_4 (M = Si or Ge) in various

* Throughout this paper : 1 mmHg \approx 13.6 \times 9.8 Pa.

J.C.S. Dalton

molar ratios either in benzene solution or as neat solutions gave rise to the exchange reactions (1)—(4). Exchange between $MCl_2(NMe_2)_2$ and MCl_4 (M = Si or Ge) was also studied, equation (5).

$$2\text{SiMe}_{2}(\text{NMe}_{2})_{2} + \text{MCl}_{4} \rightleftharpoons 2\text{SiMe}_{2}\text{Cl}(\text{NMe}_{2}) + \text{MCl}_{2}(\text{NMe}_{2})_{2} \quad (1)$$

$$SiMe_2(NMe_2)_2 + 2MCl_4 \rightleftharpoons$$

SiMe_2Cl_2 + 2MCl_3(NMe_2) (2)

$$SiMe_2(NMe_2)_2 + SiCl_4 = SiMe_2Cl_2 + SiCl_2(NMe_2)_2 \quad (3)$$

$$3\text{SiMe}_{2}(\text{NMe}_{2})_{2} + 3\text{GeCl}_{4} \rightleftharpoons 2\text{SiMe}_{2}\text{Cl}(\text{NMe}_{2}) + \\ \text{SiMe}_{2}\text{Cl}_{2} + 2\text{GeCl}_{3}(\text{NMe}_{2}) + \text{GeCl}_{2}(\text{NMe}_{2})_{2} \quad (4)$$

$$MCl_2(NMe_2)_2 + MCl_4 \Longrightarrow 2MCl_3(NMe_2)$$
 (5)

All reactions were noticeably exothermic, to give clear colourless solutions. Products, which in each case

$$A = CH_2$$
, $B = B' = NMe_2$, $M = Ti$, Sn
 $A = CH_2$, $B = B' = PPh_2$, $M = Ti$
 $A = SiMe_2$, $B = B' = NMe_2$, $M = Ti$, Zr, Hf, Sn

FIGURE 1 Six-co-ordinate geometry of the compounds $MCl_4 \cdot ABB'$

remained unchanged after thermostatting at 313 K for 24 h, were identified by chemical-shift comparisons with data from samples prepared independently: $SiMe_2(NMe_2)_2$ δ 2.48 (NCH₃), 0.1 (SiCH₃); $SiMe_2Cl(NMe_2) \delta$ 2.35

FIGURE 2 Five-co-ordinate geometry of the compounds MCl_4 ·SiMe₂(NMe₂)₂

(NCH₃), 0.33 (SiCH₃); SiMe₂Cl₂ & 0.40 (SiCH₃); SiCl₃-(NMe₂) & 2.18 (NCH₃); SiCl₂(NMe₂)₂ & 2.42 (NCH₃); GeCl₃(NMe₂) & 2.23 (NCH₃); GeCl₂(NMe₂)₂ & 2.42 (NCH₃). Sharp singlets were observed throughout, there being no evidence for line broadening as noted for some german-

ium systems.²⁵ Peak height integration confirmed the overall stoicheiometries.

Substituent exchange on silicon has been widely studied ^{26,27} and for halide-NMe₂ systems exchange is usually rapid and complete for any given ratio of reactants.²⁸ The systems studied [equations (1)—(5)] show no observable back reaction. One point of interest concerns the 1:1 reactions involving MCl₄ and (2) (M = Si or Ge). Whereas exchange of NMe₂ groups is complete in the case of silicon [equation (3)], the corresponding reaction with germanium [equation (4)] leads to a mixture of products arising from simple combination of the 2:1 and 1:2 reactions respectively. To accord with these observations we might have expected the position of equilibrium for the direct reaction of MMe₂Cl(NMe₂) and MCl₃(NMe₂) [equation (6)] to lie to the right for M = Si

$$\frac{\text{MMe}_2\text{Cl}(\text{NMe}_2) + \text{MCl}_3(\text{NMe}_2)}{\text{MMe}_2\text{Cl}_2 + \text{MCl}_2(\text{NMe}_2)_2} \quad (6)$$

but to the left for M = Ge. In both cases however, reaction was rapid and complete.

Dropwise addition of a two-fold excess of SiMe₂Cl-(NMe₂) to SnCl₄ in benzene gave (3 d) colourless crystals of SnCl₄·SiMe₂(NMe₂)₂ (Figure 1). Work-up of the remaining solution afforded SiMe₂Cl₂ as the sole silicon-containing product. A similar reaction using TiCl₄ in n-hexane gave a brown solution which on standing (24 h) slowly deposited green crystals of [TiCl₃(NMe₂)]; Si-Me₂Cl₂ was again recovered from the residual solution.

$$2SiMe_{2}Cl(NMe_{2}) \xrightarrow{} SiMe_{2}Cl_{2} + SiMe_{2}(NMe_{2})_{2}$$

$$(7)$$

$$Rapid exchange
with MCl_{4}(M = Ti)$$

$$SiMe_{2}Cl_{2} + [TiCl_{3}(NMe_{2})] \xrightarrow{decomposition} MCl_{4} \cdot SiMe_{2}(NMe_{2})_{2}$$

The slow formation of the $SnCl_4$ ·SiMe₂(NMe₂)₂ adduct is in accord with the equilibrium position for the proposed disproportionation of $SiMe_2Cl(NMe_2)$ lying well to the left [equation (7)]. Direct treatment of $SiMe_2Cl_2$ and $SiMe_2(NMe_2)_2$ gives an exothermic and rapid reaction from which $SiMe_2Cl(NMe_2)$ was isolated in essentially quantitative yield. Formation of the titanium product $[TiCl_3(NMe_2)]$ can be viewed either as a direct result of a rapid exchange reaction or *via* breakdown of $TiCl_4$ · $SiMe_2(NMe_2)_2$. The facile decomposition of the latter compared with the tin(IV) analogue has been described above.

[TiCl₃(NMe₂)], [Ti(cp)(NMe₂)₃], (3), and $[Zr(cp)_2-(NMe_2)_2]$, (4).—Dissolution of [TiCl₃(NMe₂)] in thf (tetrahydrofuran) or MeCN (solvent molecules, L) gives deep green solutions which on treatment with equimolar MCl₄ (M = Si or Ge) provide the pale yellow bis adducts TiCl₄·2L. The rapid exchange: [TiCl₃(NMe₂)] + MCl₄ \longrightarrow TiCl₄ + MCl₃(NMe₂) provides TiCl₄ which preferentially (to MCl₄) gives complex formation with excess of L. The exact nature of the green [TiCl₃(NMe₂)]thf, MeCN solutions, as distinct from the pale brown solutions formed in non-donor solvents, could not be

1267

established. Removal of solvent reliably gave tarry non-stoicheiometric materials. Addition of [TiCl₃-(NMe₂)] to a two-fold excess of (Me₂N)₃P=O (tdpo) in benzene solution gave a deep brown solution from which pale yellow crystals of trans-TiCl₄·2tdpo²⁹ slowly deposited (2 weeks). In the absence of halide exchange, the slow disproportionation $2 [TiCl_3(NMe_2)] \rightarrow [TiCl_2 (NMe_2)_2] + TiCl_4$ is proposed as the initial ratedetermining step.

The reactions of (3) and (4) with MCl_4 (M = Si, Ge, Sn, Ti, Zr, or Hf) were investigated following direct mixing in benzene solution [equation (8)]. Work-up of the resulting solutions consistently gave (a) $[Ti(cp)Cl_3]$ and $(b) [Zr(cp)_2Cl_2]$ respectively to indicate group exchange as a general theme rather than N-donor chelation as observed in reactions with metal carbonyls.¹⁵

$$[M'(cp)_{x}(NMe_{2})_{4-x}] + MCl_{4} \rightleftharpoons [M'(cp)_{x}Cl_{4-x}] + [MCl_{x}(NMe_{2})_{4-x}] (8)$$

[(a) M' = Ti, x = 1; (b) M' = Zr, x = 2]

The identities of the dimethylamino-substituted metal(IV) chloro-species proved difficult to establish and, in several cases, changed somewhat with varying reaction conditions. For equimolar addition (M = Si or Ge), removal of solvent followed by vacuum distillation gave $(a) \operatorname{MCl}(\operatorname{NMe}_2)_3 \operatorname{and} (b) \operatorname{MCl}_2(\operatorname{NMe}_2)_2$, respectively. With a large excess of MCl₄, however, MCl₃(NMe₂) was identified as the common 'second 'product. For M = Ti, reaction (8b) produced a brown solid which gave a chocolatebrown sublimate identified as the non-stoicheiometric form of 'TiCl₂(NMe₂)'; reaction (8a) also gave a brown solid which resisted sublimation and whose ¹H n.m.r. spectrum [δ 3.21 (singlet) with complex profile δ 2.0— 3.7] indicated a complex mixture of Ti(NMe₂) species. A repeat of these reactions with a four-fold excess of TiCl₄ provided green crystals of [TiCl₃(NMe₂)] as the 'second' product in both cases. Characterisation of the involatile solids formed as ' second ' products in the remaining systems (M = Sn, Zr, or Hf) proved inconclusive.

We thank the S.R.C. for the award of a research studentship (to S. R. W.).
