Bicomponent catalyst

Strong interaction

Sintering resistant

Diethanolamine dehydrogenation

## ABSTRACT

Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> catalyst was synthesized by a simple co-precipitation method, and its self-oxidation behavior after reduction reduced the particle size of Co<sub>3</sub>O<sub>4</sub>. Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> demonstrated a high performance during the dehydrogenation of diethanolamine, reaching a 96% yield of iminodiacetic in 30 min. The catalyst was characterized by XRD, XPS, TEM, SEM, and H<sub>2</sub>-TPR. The results showed that strong Cu-oxide interactions, the co-catalysis of biactive components, and the higher number of oxygen vacancies of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> were responsible for the enhanced catalytic activity during diethanolamine dehydrogenation. Co<sub>3</sub>O<sub>4</sub> particles improved the dispersion and stability of Cu NPs and inhibited the sintering of loaded Cu NPs.

## 1. Introduction

Glyphosate is the most widely used pesticide in the world and is produced mainly from iminodiacetic acid (IDA) and glycine (Gly). The IDA method was invented by Monsanto, which currently uses it to produce glyphosate in all of its factories around the world [1]. The key reaction in an alternative, cost-efficient route for glyphosate synthesis is the dehydrogenation of diethanolamine (DEA) to form disodium iminodiacetic acid (DSIDA). Cu-based catalysts are commonly used during this reaction [2,3], but since slurry kettle-type reactions are used, the catalyst tends to lose its activity because active components easily oxidize and aggregate. During the later stages of catalyst used, the reactivity and selectivity of the catalyst typically decrease.

The development of stable and efficient catalysts is challenging, and many methods have been developed to improve the catalytic activity and anti-sintering property of Cu-based catalysts, including optimizing the preparation process of Cu NPs, selecting and pretreating carrier materials, and exploiting the constraining effect of porous channels and materials on Cu NPs [4–6]. The strategies and methods for suppressing the sintering of supported Cu NPs exploit strong metal–support interactions (SMSI) between Cu NPs and oxide supports [7]. The most effective method to improve a catalyst's activity is to increase its number of active components and active sites. Therefore, novel high-performance Cu-based catalysts can be developed by introducing new

active metal oxides to construct dual-active components. Biactive components usually have higher catalytic activities than single-metal catalysts due to their synergistic catalytic effects [8]. Additionally, the introduction of new active oxides can create new environments and catalyst morphologies that can improve the catalytic performance. For example, Ga<sub>2</sub>O<sub>3</sub>/Cu/ZrO<sub>2</sub> catalysts can improve the selectivity of the synthesis of methanol from CO<sub>2</sub>, increase the catalytic activity, and improve the dispersion of Cu NPs [9]. Active sites are often oxygen vacancies or coordinatively unsaturated metal cations located at the interface between Cu and oxide [10]. Therefore, the selection of active components and SMSI effects between Cu and the oxide carrier are very important for improving the activity and stability of a catalyst.

The structure and properties of nanoscale oxide carriers significantly affect the dispersion and electronic properties of Cu particles [11]. In many homogeneous catalytic reactions, ZrO<sub>2</sub>-supported metal nanoparticles have good anti-sintering properties. As a carrier, ZrO<sub>2</sub> provides a charge buffer for the gain and loss of electrons of Cu. Although it is not directly involved in catalysis, it can effectively improve the activity of Cu-based catalysts [12]. As a structural stabilizer, ZrO<sub>2</sub> can prevent the sintering of copper NPs and prolong the service life of catalysts [13]. Co oxides are generally the most suitable alternatives to noble metal catalysts because of abundant cobalt resources and their excellent activity during catalytic oxidation [14–19]. For example, when used as a catalyst for the hydrolysis of ammonia borane to

hydrogen, Cu/Co<sub>3</sub>O<sub>4</sub> showed excellent catalytic oxidation performance and could be reused 10 times without a significant loss in its catalytic performance [20]. Cu NP catalysts supported on Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> may be an ideal dual-active catalyst with an SMSI effect for the dehydrogenation of diethanolamine.

Therefore, Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> was designed and synthesized with an additional active component of Co<sub>3</sub>O<sub>4</sub> to form a catalyst with two active components. Small Co<sub>3</sub>O<sub>4</sub> particles were grown on the surface of ZrO<sub>2</sub> by reduction and self-oxidation. Moreover, irregular and fine Co<sub>3</sub>O<sub>4</sub> particles confined the Cu NPs to the surface of ZrO<sub>2</sub>. Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> showed good catalytic activity and stability when used to catalyze the dehydrogenation of diethanolamine. Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> is an excellent catalyst with controllable morphology and provides an example of a new bicomponent dehydrogenation catalyst.

## 2. Experimental section

### 2.1. Synthesis of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>

ZrOCl<sub>2</sub>·8H<sub>2</sub>O (6.44 g) was dissolved in 500 mL ultra-pure water, and 5 g NaOH was dissolved in 200 mL water. The NaOH solution was slowly added to the Zr salt solution and continuously stirred. After addition, the solution was stirred for 3 h to form a Zr(OH)<sub>2</sub> colloidal solution. CoCl<sub>2</sub>·2H<sub>2</sub>O (1.19 g) and 2.42 g Cu(NO<sub>3</sub>)<sub>2</sub>·3H<sub>2</sub>O were dissolved in 200 mL ultrapure water and stirred and then slowly added to the Zr(OH)<sub>2</sub> colloidal solution and continuously stirred. After addition, the mixture was stirred for 12 h and aged for an additional 4 h. The precipitate was filtered, washed, and dried in an oven at 50 °C for 12 h. Then, the dried solid was ground and roasted in a muffle furnace at 550 °C for 4 h to obtain the catalyst precursor CuO/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>. The precursor CuO/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> was placed into a tubular furnace and reduced at 240 °C for 4 h at a heating rate of 3 °C/min. When cooled to room temperature, the catalyst was removed from the tube furnace, and CoO was allowed to self-oxidize for 1 h to obtain Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> catalyst.

### 2.2. Catalytic activity evaluation

10 g Diethanolamine, 2 g catalyst, and 8.5 g sodium hydroxide (dissolved in 80 mL deionized water) were added to a high-pressure reactor. The airtightness of the reactor was checked, and then N<sub>2</sub> was passed and emptied 5–6 times before pressurizing to 1 MPa. The temperature was raised to 160 °C at a heating rate of 4 °C/min, and stirring was carried out at a speed of 400 rpm. The volume of hydrogen discharged was measured by a rotameter. The exhaust valve was opened when the air pressure reached 1.5 MPa and then closed when the pressure dropped to 1 MPa. The volume and exhaust temperature of each exhaust were recorded. During reactions, if the pressure in the reactor did not change for 20 min, the reaction was regarded as complete. Liquid chromatography was used for qualitative analysis. The yield of iminodiacetic acid was calculated using a strong anion exchange column (Hypersil SEX, 5 μm, 4.6 mm × 250 mm). The calculation of the yield of iminodiacetic acid is described in detail in the Supporting Information.

## 3. Results and discussion

Fig. 1 shows the XRD patterns of the catalysts. The Cu grain size in the catalyst was calculated using the Scherrer equation and the half-peak width of the highest diffraction peak of each material. Diffraction peaks of ZrO<sub>2</sub> were observed at 30.5°, 34.7°, 50.8°, and 60.9° (JCPDS no. 37-1484). Metallic Cu peaks appeared at 2θ values of 43.3° and 50.4°, which corresponded to the crystal planes of Cu(111) and Cu(200), respectively (JCPDS no. 04-0836). However, no metallic Cu peaks were detected in the pattern of Cu/Co<sub>3</sub>O<sub>4</sub>, indicating that the copper species may be amorphous and highly dispersed on the carrier

Fig. 1. XRD patterns of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>, Cu/Co<sub>3</sub>O<sub>4</sub>, and Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> catalysts.

[21]. The characteristic peaks of Co<sub>3</sub>O<sub>4</sub> were observed at 31.3°, 36.8°, 38.5°, 44.8°, 59.5°, and 65.2° [22], which were respectively indexed to the (111), (220), (311), (222), and (400) planes. The Cu nanoparticle size in Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> was 4.7 nm as calculated from the Scherrer equation. In addition, no characteristic diffraction peaks associated with Co<sub>3</sub>O<sub>4</sub> were observed for Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>, possibly because it was amorphous and highly dispersed on ZrO<sub>2</sub>. By comparing Cu/Co<sub>3</sub>O<sub>4</sub> and Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>, it can be seen that a wider FWHM (full width at half maximum) of the Co<sub>3</sub>O<sub>4</sub> (220) diffraction peak was observed in Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>, indicating a smaller particle size. The results show that the size of Co<sub>3</sub>O<sub>4</sub> was greatly reduced when Co<sub>3</sub>O<sub>4</sub> was grown on the surface of ZrO<sub>2</sub> by reduction and self-oxidation.

Fig. 2(a) shows the SEM images of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>. The Co<sub>3</sub>O<sub>4</sub> prepared by reductive self-oxidation had a small size, consistent with the XRD results. Fig. 2(b) are the TEM images of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>. According to Fig. 2(b), the diameter of Co<sub>3</sub>O<sub>4</sub> was about 10 nm, and Cu and Co<sub>3</sub>O<sub>4</sub> were dispersed on the surface of ZrO<sub>2</sub>.

The H<sub>2</sub>-TPR profiles of Cu/ZrO<sub>2</sub>, Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>, and Cu/Co<sub>3</sub>O<sub>4</sub> are displayed in Fig. 3. Cu/ZrO<sub>2</sub> samples showed two low-temperature reduction peaks near 130 °C and 179 °C. The reduction peak at 130 °C was caused by the reduction of highly-dispersed CuO on the surface of the catalyst, while the reduction peak at 179 °C was caused by the reduction of crystalline CuO. Another reduction peak observed at 200 °C was caused by the reduction of Cu<sup>2+</sup> in the ZrO<sub>2</sub> lattice. The two low-temperature reduction peaks of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> samples near 126 °C and 135 °C were caused by the reduction of highly-dispersed CuO on the catalyst surface, while the reduction peaks at 162 °C were caused by the reduction of crystalline CuO. The reduction temperature stability of Cu species in Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> decreased significantly compared with Cu/ZrO<sub>2</sub>. This indicates that the introduction of Co<sub>3</sub>O<sub>4</sub> improved the dispersion of Cu NPs and that the particle size was small. The overall reduction peak temperature of Cu/Co<sub>3</sub>O<sub>4</sub> Cu NPs was higher than that of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> due to the strong interaction between Cu and the Co<sub>3</sub>O<sub>4</sub> carrier. The peak at 200–260 °C was attributed to the reduction of Co<sup>3+</sup> to Co<sup>2+</sup> in Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> and Cu/Co<sub>3</sub>O<sub>4</sub> [23]. During this process, Co<sub>3</sub>O<sub>4</sub> in Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> was reduced to CoO, thus decreasing the amount of Co<sub>3</sub>O<sub>4</sub>. During self-oxidation, CoO self-oxidized to small Co<sub>3</sub>O<sub>4</sub> particles, which grew on the surface of ZrO<sub>2</sub>.

The influence of the surface elemental composition and chemical state on catalyst properties was studied using XPS. Fig. 4(a) shows the bimodal Co(2p) spectrum of Co<sub>3</sub>O<sub>4</sub>. In particular, peaks of Co 2p<sub>3/2</sub> and Co 2p<sub>1/2</sub> were found at 779.2–780.2 eV and 794.7–796.6 eV, respectively. The energy differences between the peak values of Co 2p<sub>3/2</sub> and Co 2p<sub>1/2</sub> of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>, Cu/Co<sub>3</sub>O<sub>4</sub>, and Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> were

Fig. 2. The SEM images of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> (a); TEM images of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> (b).

Fig. 3. H<sub>2</sub>-TPR patterns of the catalysts.

respectively 16.4, 15.6, and 15 eV, indicating the existence of Co<sub>3</sub>O<sub>4</sub> [24]. The XPS peaks of Cu 2p were observed at 933.1/933.4 eV and 953.0/953.6 eV with strong shake-up satellite peaks in the patterns of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> and Cu/Co<sub>3</sub>O<sub>4</sub>. The satellite peaks indicated that the Cu species in Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> and Cu/Co<sub>3</sub>O<sub>4</sub> was Cu(II) [25] (Fig. S1). Fig. 4(b) shows the deconvolution peaks of O of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>, Cu/Co<sub>3</sub>O<sub>4</sub>, and Cu/ZrO<sub>2</sub> samples. The patterns of all three samples contained diffraction peaks near 529.8 eV and 531.5 eV, which respectively corresponded to lattice O and defect oxygen vacancies (dissociated adsorptive oxygen). By integrating the spectrum of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>, oxygen vacancies were determined to account for 29.4%, 28.0%, and 15.0% of all O present in Cu/Co<sub>3</sub>O<sub>4</sub> and Cu/ZrO<sub>2</sub>, respectively. Co<sub>3</sub>O<sub>4</sub> may have grown on the surface of ZrO<sub>2</sub> to produce highly-active defective oxygen vacancies. The oxygen vacancies content of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> was the highest, leading to its excellent catalytic activity, which was conducive to the rapid dehydrogenation of diethanolamine.

The catalysts were used in the dehydrogenation of diethanolamine to prepare iminodiacetic acid. The catalytic activity performance results are shown in Table 1. Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> had the highest activity and fastest reaction time compared with literature and commercial catalysts. This was caused by Cu and Co<sub>3</sub>O<sub>4</sub> co-catalysis and the additional oxygen vacancies which can quickly absorb diethanolamine. Cu and Co<sub>3</sub>O<sub>4</sub> promoted catalysis by forming an aldehyde intermediate by  $\alpha$ -H cleavage. Second, the introduction of Co<sub>3</sub>O<sub>4</sub> increased the density of active sites which helped form surface oxygen vacancies by improving the adsorption-activation of reactant molecules over active sites due to strong metal-oxide interactions. The abundant oxygen vacancies and Co<sub>3</sub>O<sub>4</sub> species dramatically enhanced the oxidation of hydroxyls to

Fig. 4. XPS spectra of Co 2p (a) and O (b).

**Table 1**  
Activity test results of samples in the dehydrogenation of diethanolamine.

Catalyst	IDA Yield (%)	Reaction time/min	Reaction temperature/°C
Cu/ZrO <sub>2</sub>	92	150	160
Cu/Co <sub>3</sub> O <sub>4</sub> -ZrO <sub>2</sub>	96	30	160
Cycle 2 of Cu/Co <sub>3</sub> O <sub>4</sub> -ZrO <sub>2</sub>	95	32	160
Cu/Co <sub>3</sub> O <sub>4</sub>	90	240	160
Co <sub>3</sub> O <sub>4</sub> -ZrO <sub>2</sub>	60	480	170
CZ@CN <sup>[2]</sup>	92	90	160
Cu/ZrO <sub>2</sub> -RGO <sup>[3]</sup>	90	75	160
Raney Cu	98	600	160
ZrO <sub>2</sub>	0	600	160

aldehyde intermediates. In addition, the much larger surface area of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> (61 m<sup>2</sup>/g) than Cu/ZrO<sub>2</sub> (23 m<sup>2</sup>/g) was possibly due to the addition of transition metals, which were 11.1% (Cu) and 5.8% (Co) (Table S1). Therefore, the Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> catalyst showed excellent catalytic performance, and a 96% yield of IDA was achieved within 30 min.

To determine whether Co<sub>3</sub>O<sub>4</sub> had a catalytic oxidation effect on diethanolamine, Co<sub>3</sub>O<sub>4</sub> was loaded onto ZrO<sub>2</sub> to prepare a Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> catalyst. A yield of 60% was obtained after a 480 min reaction. Since ZrO<sub>2</sub> had no catalytic effect on the reaction, it was determined that Co<sub>3</sub>O<sub>4</sub> was responsible for the catalytic oxidation during the reaction. Compared with Cu/ZrO<sub>2</sub>-RGO catalysts in the literature, the reaction time decreased by 60% from 75 min to 30 min.

TEM, XRD, and XPS were used to characterize catalysts after the reactions to explore the state of the active species after a reaction. Fig. S2(b) shows that Co<sub>3</sub>O<sub>4</sub> contained small particles on the surface of ZrO<sub>2</sub> before and after the reaction. The particle size was 10 nm after the reaction, which was the same as the fresh catalyst. Fig. S2(d) shows XRD patterns of fresh and used Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> catalysts. Compared with the fresh catalyst, the position and strength of the Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> diffraction peak did not significantly change after the reaction, indicating that Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> was stable because strong interactions between the metal prevented agglomeration during sintering. Fig. S2(e, f) shows the deconvoluted Co 2p<sub>3/2</sub> peaks of fresh and post-reaction catalyst. The intensity of the peaks at 781.3 eV and 786.3 eV increased after the reaction, indicating that Co(OH)<sub>2</sub> was formed on the catalyst surface after the reaction [26,27].

#### 4. Conclusions

A CuO/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> precursor was obtained by co-precipitation, and a bicomponent Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> catalyst was successfully prepared by reduction and self-oxidation. When used in the dehydrogenation of diethanolamine to prepare IDA, the Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> catalyst showed excellent catalytic performance, and a 96% yield of IDA was achieved within 30 min. The inclusion of a biactive component was key to increasing the catalytic activity of Cu/Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub> catalysts during diethanolamine dehydrogenation. It was also important to include Co<sub>3</sub>O<sub>4</sub> to increase the number of oxygen vacancy defects in the catalyst during the catalytic dehydrogenation of diethanolamine. The strong interactions between metal (Cu) and oxide (Co<sub>3</sub>O<sub>4</sub>-ZrO<sub>2</sub>) helped improve the stability and activity of the catalyst. The results of this study suggest that Co<sub>3</sub>O<sub>4</sub> can be used as an active component to enhance the performances of Cu-based nanocatalysts, and this work provides a new strategy for developing other advanced dehydrogenation catalysts.
