The oxidative addition reaction of $Pt(PEt_3)_4$ with $Cl_2C=PN(SiMe_3)_2$ at low temperature (-50 °C) forms the η^1 -phosphavinyl complex *cis*-Cl(Et₃P)₂Pt[C(Cl)=PN(SiMe_3)_2] (Ia), which isomerizes to the *trans*-isomer (**Ib**) upon warming to 0 °C; the structure of **Ib** was determined by X-ray diffraction studies. Complex **Ib** reacts with Pt(PEt₃)₂Cl₂ in the presence of 3 equiv of sodium benzophenone to generate the bridging, dinuclear η^1, η^2 -cyaphide complex Cl(Et₃P)₂- $Pt(\mu - \eta^1, \eta^2 - C \equiv P)Pt(PEt_3)_2$ (II) in good yield, providing a much simpler and higher yield preparation of **II**, which was synthesized and characterized previously by a more circuitous route. Compound II reacts with 0.5 equiv of $[Cl_2Pt(PEt_3)]_2$ or with 1 equiv of $W(CO)_5(THF)$ to generate the trinuclear metal-cyaphide complexes $Cl(Et_3P)_2Pt[\mu-\eta^1,\eta^1,\eta^2-C \equiv P{Pt(PEt_3) (Cl)_2$]Pt(PEt₃)₂ (III) and Cl(Et₃P)₂Pt[μ - η ¹, η ¹, η ²-C=P{W(CO)₅}Pt(PEt₃)₂ (IV), respectively, in which the lone pair of electrons on the $C \equiv P$ phosphorus atom is coordinated to a Pt- $(PEt_3)(Cl)_2$ fragment in the former and to a $W(CO)_5$ fragment in the latter; the structure of IV was determined by X-ray diffraction studies. Compound II also reacts with MeI to form the methyl isocyaphide complex $(Cl)(Et_3P)Pt(\mu-C=PMe)Pt(PEt_3)_2(I)$ (Vc), in which the cyaphide ($C \equiv P^{-}$) ligand is converted to a methyl isocyaphide ($C \equiv PMe$) ligand in a semibridging coordination mode. When compound II is reacted with MeOTf, the product is the cationic isocyaphide complex $[(Cl)(Et_3P)_2Pt(\mu-\eta^1,\eta^2-C\equiv PMe)Pt(PEt_3)_2](OTf)$ (Va), which is likely coordinated in an η^1 , η^2 -bridging mode. Compound **Va** reacts with NaI to form **Vc**, which suggests that **Va** forms as an intermediate before **Vc** in the reaction of **II** with MeI.

Introduction

Studies involving phosphorus analogues of common organic ligands have evolved at a very rapid pace recently, and coordination compounds of C-P analogues of almost all C-C multiple bond ligands are now known, including phosphaalkenes, phosphaalkynes, phosphaallyls, phosphaallenes, phosphabutadienes, phosphacyclopropenes, phosphacyclobutadienes, phosphacyclopentadienyls, and phosphaarenes.¹⁻⁶ However, phosphorus analogues of the well-studied cyanide $(C \equiv N)^{-1}$ and isocyanide (C=NR) ligands have been limited.7-9

These phosphorus compounds have been calculated to be high energy species; the heat of formation of $(C \equiv P)^{-1}$ (cyaphide anion) is calculated to be ca. 40 kcal/mol less exothermic than that of $(C=N)^{-}$,¹⁰ and C=PH (isocyaphide) is calculated to be 85 kcal/mol less stable than its isomer H−C≡P (phosphaalkyne).¹¹ Nevertheless, we recently succeeded in preparing the first example of a coordinated isocyaphide ligand by oxidative addition of the C–Cl bond in the phosphavinyl complex 1 (eq 1) to

generate a diplatinum complex [(Cl)(Et₃P)Pt(μ -C=PR)- $Pt(PEt_3)_2(Cl)$] (2), in which the isocyaphide ligand exhibits a semibridging coordination mode.⁹ However, this preparation was limited by the few examples of dichlorophosphaalkenes that are available and by the

bulky R-groups that are incorporated in these reagents. More recently, Weber and co-workers reported the synthesis (eq 2) of some diiron complexes containing

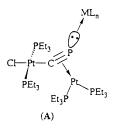

symmetrically bridged isocyaphide ligands (3) by a different route.⁷ In these reactions, the isocyaphide products were stable only when bulky R-groups were present on phosphorus. We also obtained the first example of a cyaphide complex $(Et_3P)_2ClPt(C \equiv P)$ (4) from a reaction (eq 3) of the phosphavinyl complex (1)

with Pd(PEt₃)₄, in which the Mes* group was transferred from phosphorus to palladium forming $(Et_3P)_2$ -(Cl)Pd(Mes*) as a side product.⁹ Compound **4** could only be characterized by NMR spectroscopy but reacted (eq 3) with Pt(PEt₃)₄ to generate the bridging, dinuclear η^1, η^2 -cyaphide complex Cl(Et₃P)₂Pt(μ - η^1, η^2 -C=P)Pt-(PEt₃)₂ (**II**), which was characterized by X-ray diffraction studies.

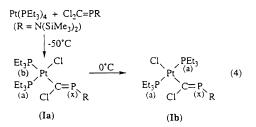

We describe in the present paper a high-yield preparation of complex **II** utilizing a one-step reaction from the phosphavinyl complex *trans*-Cl(Et₃P)₂Pt[C(Cl)=PN-(SiMe₃)₂] **(Ib**), which has much different reactivity than the analogous phosphavinyl complex *trans*-Cl(Et₃P)₂Pt-[C(Cl)=PMes*] **(1)**.¹² We also investigate functionalization of the cyaphide ligand in complex **II** by reaction of the accessible lone pair of electrons on the C=P phosphorus atom. During the course of these studies, we have isolated the first examples of trinuclear metal– cyaphide compounds **(A)** that were formed by coordinat-

ing the C=P phosphorus atom in **II** to other transition metal fragments. We have also found that the cyaphide ligand in **II** can be easily converted to an alkyl isocyaphide ligand by reaction with alkylating agents, constituting the first examples of cyaphide–isocyaphide conversions and demonstrating that isocyaphide ligands with less bulky alkyl R-groups can be stabilized on transition metals.

Results and Discussion

Synthesis of *trans*-Cl(Et₃P)₂Pt[C(Cl)=PN(SiMe₃)₂] (**Ib**). The reaction (eq 4) of Pt(PEt₃)₄ with Cl₂C=PN-

 $(SiMe_3)_2$ in THF or hexanes at -50 °C immediately and quantitatively forms the η^1 -phosphavinyl complex *cis*-Cl(Et₃P)₂Pt[C(Cl)=PN(SiMe₃)₂] (Ia) by oxidative addition of one of the C-Cl bonds; upon warming the solution to 0 °C, the *cis*-isomer completely rearranges to the *trans*-isomer (Ib). Some formation of Pt(PEt₃)₂-Cl₂ also occurs during this reaction. This cis-trans isomerization is quite similar to that in the analogous phosphavinyl complex Cl(Et₃P)₂Pt[C(Cl)=PMes*], in which both the cis- and trans-isomers were isolated and characterized.¹² The structure and ³¹P NMR spectrum of Ib are very similar to those of trans-Cl(Et₃P)₂Pt-[C(Cl)=PMes*] (1), but they differ in reactivity. For instance, compound 1 rearranges to Mes*C≡P and Pt(PEt₃)₂Cl₂ after 24 h in THF at room temperature, whereas Ib is stable in THF for weeks at room temperature, although a small amount of Pt(PEt₃)₂Cl₂ does form in this time. Further, compound 1 undergoes a second C-Cl oxidative addition reaction (eq 1) with Pt(PEt₃)₄ in 24 h at room temperature to form the isocyaphide complex [(Cl)(Et₃P)Pt(*µ*-C=PMes*)Pt(PEt₃)₂-(Cl)] (2); a similar reaction between Ib and Pt(PEt₃)₄ does not form the $N(SiMe_3)_2$ analogue of compound 2, but results in decomposition to a complex mixture of unidentified products.

Compound Ia was characterized by ³¹P and ³¹P{¹H} NMR spectra; compound Ib was characterized by ³¹P and ³¹P{¹H} NMR spectra, elemental analysis, electrospray mass spectrometry, and X-ray diffraction studies. The signals corresponding to P(x) in the ³¹P NMR spectra of Ia and Ib were assigned by their characteristic downfield chemical shifts of 225.1 and 222.3 ppm, respectively, and by their proton-coupled ³¹P NMR spectra, in which these signals do not show any proton coupling, while the signals corresponding to the PEt₃ groups are greatly broadened. The P(x) peak in **Ia** is split into a doublet of doublets $({}^{3}J_{P(x)P(a)} = 8.3 \text{ Hz},$ ${}^{3}J_{P(x)P(b)} = 33.0$ Hz) by the two inequivalent PEt₃ groups and exhibits platinum satellites with ${}^{2}J_{P(x)Pt} = 410$ Hz. The P(x) peak in **Ib** is split into a triplet $({}^{3}J_{P(x)P(a)} =$ 20.0 Hz) by the two equiv PEt₃ groups and exhibits a larger ¹⁹⁵Pt–P coupling constant (${}^{2}J_{P(x)Pt} = 676$ Hz) than in **Ia**. In **Ia**, the PEt₃ ligand that is *trans* to the C(Cl)= PN(SiMe₃)₂ group is assigned to P(b) at δ 10.1 ppm and the *cis* PEt₃ ligand is assigned to P(a) at δ 5.6 ppm based on the larger coupling constant ${}^{3}J_{P(x)P(b)} = 33.0$ Hz between P(x) in the C(Cl)=PN(SiMe₃)₂ group and the trans PEt₃ group P(b). These ³¹P NMR data are analogous to those¹² obtained for *cis*-Cl(Et₃P)₂Pt[C(Cl)= PMes^{*}] (δ (P(x)): 224.0 (dd, ${}^{3}J_{P(x)P(a)} = 12.3$ Hz, ${}^{3}J_{P(x)P(b)}$ = 46.3 Hz, ${}^{2}J_{P(x)Pt}$ = 365.4 Hz) and *trans*-Cl(Et₃P)₂Pt- $[C(Cl)=PMes^*]$ (1) ($\delta(P(x))$: 223.3 (t, ${}^{3}J_{P(x)P(a)} = 25.2$ Hz, $^{2}J_{P(x)Pt} = 657.7$ Hz), which indicates that the compounds are isostructural and that the N(SiMe₃)₂ group does not impart dramatic differences in the bonding compared with the Mes* group. However, to more thoroughly compare the bonding properties in these complexes, the structure of **Ib** was determined by X-ray diffraction studies and compared with the previously determined structure of compound $1.^{12}$

X-ray Crystal Structure of trans-Cl(Et₃P)₂Pt-[C(Cl)=PN(SiMe₃)₂] (Ib). A thermal ellipsoid drawing of Ib (Figure 1) shows that the complex is isostructural with the previously characterized compound trans-Cl- $(Et_3P)_2Pt[C(Cl)=PMes^*]$ (1). The platinum atom is in a square-planar environment as defined by the two PEt₃, Cl, and [C(Cl)=PR] ligands; the sum of angles around the platinum atom is 360.0° . The C(1)-P(1) distance of 1.690(7) Å is the same as that (1.678(5) Å)in compound 1 and the C=P distance (1.685(2) Å) in the free phosphaalkene Cl₂C=PN(SiMe₃)₂.¹³ The Pt-C(1) distance in **Ib** (1.990(7) Å) is slightly shorter than the corresponding distance (2.013 (4) Å) in $1.^{12}$ The nitrogen atom in **Ib** is in a trigonal planar environment, and the P(1)-N(1)-Si(1)-Si(2) plane is almost orthogonal (96.4°) to the plane defined by Pt, Cl(1), C(1), P(1), and N(1). This orthogonality rules out any conjugative effects from the nitrogen lone pair; in a series of X-raydetermined structures of phosphaalkenes containing NR₂ groups on phosphorus, orthogonal NR₂ groups were found to show no conjugative effects with the C=P double bond.¹⁴ If the [C(Cl)=PR] ligands in **1** and **Ib** were significantly different, the bond lengths between platinum and the *trans* ligands (Cl(2)) would be affected by this difference. However, the Pt–Cl(2) length in **Ib** (2.373(2) Å) is the same within error as that (2.377(2) Å)Å) in **1**. Thus, a comparison of the structures of **1** and **Ib** indicates that the N(SiMe₃)₂ and Mes^{*} groups show similar structural effects in phosphavinyl complexes of the type *trans*-Cl(Et₃P)₂Pt[C(Cl)=PR].

Preparation of Cl(Et₃P)₂Pt(\mu-\eta¹,\eta²-C=**P**)**Pt(PEt₃)₂** (**II**). The reaction (eq 5) of 1.05 equiv of *trans*-Cl(Et₃P)₂-Pt[C(Cl)=PN(SiMe₃)₂] (**Ib**) and 1 equiv of Pt(PEt₃)₂Cl₂ with 3 equiv of sodium benzophenone ketyl in THF forms the bridging, dinuclear cyaphide complex Cl-(Et₃P)₂Pt(μ - η ¹, η ²-C=P)Pt(PEt₃)₂ (**II**) in good yield (79%).

This preparation is much simpler than that (eq 3) originally reported. Furthermore, this reaction can be done on a several gram scale and gives excellent yields of complex **II** in pure, crystalline form.

To gain an understanding of how this reaction proceeds, several different stoichiometries of the reagents were investigated, as was the order of addition. The use of 3 equiv of the Na/benzophenone ketyl reducing agent was found to be optimum, as more equiv caused decomposition, while fewer resulted in incomplete reaction, which suggests that the two chlorides from Pt-(PEt₃)₂Cl₂ and one chloride from **Ib** are removed as NaCl. The N(SiMe₃)₂ group is possibly removed as

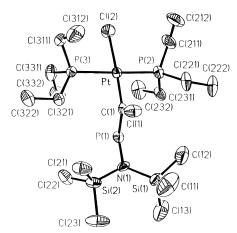

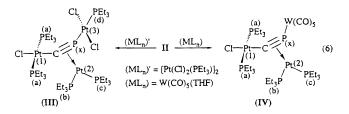

Figure 1. Thermal ellipsoid drawing of *trans*-Cl(Et₃P)₂-Pt[C(Cl)=PN(SiMe₃)₂] (**Ib**).

(SiMe₃)₂N-N(SiMe₃)₂, although this was not investigated. The reaction of *trans*-Cl(Et₃P)₂Pt[C(Cl)=PMes*] (1) with $Pt(PEt_3)_2Cl_2$ and 3 equiv of sodium benzophenone ketyl also resulted in the formation of II, but it produced impurities that could not be separated. To investigate the role of the reducing agent, a reaction was attempted between **Ib** and Na/benzophenone ketyl without any Pt(PEt₃)₂Cl₂ present; no reaction was apparent after 6 h. Also, if Pt(PEt₃)₂Cl₂ is first combined with Na/benzophenone ketyl followed by addition of **Ib**, a ³¹P NMR spectrum shows that **Ib** is unreacted in solution. Evidently, both **Ib** and Pt(PEt₃)₂Cl₂ must be present during the addition of the reducing agent for this reaction to occur. The reduction of $Pt(PEt_3)_2Cl_2$ in the presence of ethylene is known to produce Pt(PEt₃)₂- (C_2H_4) ,¹⁵ and it has been reported that if a suitable ligand is not present in solution, Pt(PEt₃)₂ fragments tend to oligomerize into Pt(0) clusters.¹⁶ It is possible that the $Pt(PEt_3)_2$ fragment that is generated in eq 5 coordinates to the C=P double bond of **Ib** and activates the carbon-bound Cl toward reduction by a third equiv of Na/benzophenone ketyl, while in the absence of Ib the Pt(PEt₃)₂ oligomerizes and does not react with **Ib**. Reactions similar to that in eq 5 were attempted between **Ib** and Pt(PPh₃)₂Cl₂, Pt(Pi-Pr₃)₂Cl₂, Pt(PCy₃)₂-Cl₂, and Pt(depe)Cl₂; in all cases, compound **Ib** remained unreacted in solution, indicating that this reaction is not general for other phosphines.

Preparation of Trinuclear Metal–**Cyaphide Complexes.** The cyaphide ligand that is coordinated to two platinum centers in complex **II** contains a lone pair of electrons on the C=P phosphorus atom that is a potential site for further coordination. Accordingly, the reactions (eq 6) of either 0.5 equiv of $[Pt(Cl)_2(PEt_3)]_2$ or

1 equiv of W(CO)₅(THF) with II in THF at room

temperature afford the first examples of trinuclear metal-cyaphide complexes $Cl(Et_3P)_2Pt[\mu-\eta^1,\eta^1,\eta^2-C \equiv$ $P{Pt(PEt_3)(Cl)_2}$ Pt(PEt_3)₂ (III) and $Cl(Et_3P)_2Pt[\mu$ - η^1, η^1, η^2 -C=P{W(CO)₅}Pt(PEt_3)₂ (IV), respectively. Complex III forms immediately after the addition of $[Pt(Cl)_2(PEt_3)]_2$ to **II** and a ³¹P NMR spectrum of the reaction mixture showed practically quantitative conversion to III with a small amount of Pt(PEt₃)₂Cl₂ formed as a byproduct; complex III could not be isolated in pure form, as it decomposes under vacuum to unidentified materials, presumably through loss of PEt₃. In the reaction of $W(CO)_5(THF)$ with **II**, the formation of complex IV is complete after 1 h, and a small amount of $W(CO)_5(PEt_3)$ forms as a byproduct that is easily separated. These reactions are similar to those of the η^2 -coordinated phosphaalkyne complexes (R₃P)₂Pt(η^2 -R–C=P), in which η^2 -coordination of the phosphaalkyne to the platinum fragment enhances the coordinating ability of the lone pair of electrons on phosphorus.^{3,17}

Compounds III and IV were characterized by ³¹P and ${}^{31}P{}^{1}H{}^{\overline{1}}$ NMR spectroscopy, and the structure of complex IV was determined by X-ray diffraction studies. The ³¹P NMR data for these compounds are compared in Table 1 along with the starting cyaphide complex (II) and the methyl isocyaphide complex (Va), which is a cationic complex of similar structure (see below). In all of these complexes, the peaks corresponding to P(x) are conveniently assigned by proton-coupled ³¹P NMR spectroscopy, in which the P(x) signals remain sharp, while the PEt₃ signals are broadened by coupling to the ethyl protons. Complex III exhibits five distinct signals in its ³¹P NMR spectrum; peaks corresponding to P(x) at δ 111.2, P(a) at δ 5.0, P(b) at δ 15.9, and P(c) at δ 17.2 ppm were assigned on the basis of similar signals in the ³¹P NMR spectrum of II, while the peak corresponding to P(d) at δ 5.2 ppm was assigned to the PEt₃ group in the Pt(PEt₃)(Cl)₂ fragment that is coordinated to the $C \equiv P$ phosphorus atom. The peak for P(x) in **II** is split into a doublet of doublet of triplets, while the same peak in III is now split into a doublet of doublet of doublet of triplets; the extra splitting is from the PEt₃ ligand on the Pt(PEt₃)(Cl)₂ fragment (${}^{2}J_{P(x)P(d)} = 472.3$ Hz). This is a very large two-bond P-P coupling constant that is indicative of a *trans*-orientation between P(d) and P(x), similar to the $trans^2 J_{PP} = 557$ found in the bridging phosphaalkyne complex Mo₂(CO)₄(Cp)₂{t-BuCP[Pt(PEt₃)- $(Cl)_2$]¹⁸ and to the values of *trans*-² $J_{PP} = 462-483$ Hz measured in a series of trans-[PtCl₂(PR₃)(PR'₃)] complexes.¹⁹ The coordination of the Pt(PEt₃)(Cl)₂ fragment to compound II also imparts a large change on the twobond coupling constant between P(x) and the *trans*-like PEt₃ ligand P(b); the value of ${}^{2}J_{P(x)P(b)} = 13.7$ Hz in **II** increases to ${}^{2}J_{P(x)P(b)} = 148.0$ Hz in **III**. This effect has also been seen in η^2 -phosphaalkyne complexes; in the complex [Pt(dppe)(η^2 -t-BuC=P)], the coupling constant between the C=P phosphorus and the *trans*-P atom is 28.1 Hz, but when a $Cr(CO)_5$ fragment is coordinated to the C=P phosphorus atom, this value increases to 177.5 Hz.¹⁷ In fact, all of the couplings between P(x)and the other phosphorus signals are increased upon coordination of the Pt(PEt₃)(Cl)₂ group (see Table 1). Evidently, the cyaphide phosphorus atom undergoes a change in hybridization upon coordination to the metal fragment, which gives the phosphorus more s-orbital character in its bond with the metal.

Complex IV exhibits four distinct signals in its ³¹P NMR spectrum; the peaks corresponding to P(a) at δ 3.1, P(b) at δ 16.6, and P(c) at δ 13.9 ppm were assigned based on similar signals in the ³¹P NMR spectrum of II and III, while the peak at δ 41.4 ppm was assigned to P(x) based on a sharp proton-coupled ³¹P NMR signal and the doublet of doublet of triplets splitting pattern. The chemical shift of 41.4 ppm is 66 ppm upfield from that of P(x) in compound II and is similar to the upfield shift of 42 ppm that was measured upon coordination of a $W(CO)_5$ fragment to the C=P phosphorus atom in the η^2 -phosphaalkyne complex [Pt(dppe)(η^2 -t-BuC= P)].¹⁷ The coordination of the $W(CO)_5$ group to complex **II** results in increased ³¹P⁻³¹P coupling constants (see Table 1) similar to those for III. The two-bond coupling constant between P(x) and the trans-like PEt₃ ligand P(b) is again very large, ${}^{2}J_{P(x)P(b)} = 152.9$ Hz, and similar to that $({}^{2}J_{P(x)P(b)} = 148.0 \text{ Hz})$ in **III**. Only one set of platinum satellites (${}^{2}J_{P(x)Pt(1)} = 507$ Hz) could be distinguished for P(x) in compound IV because of the complexity of this signal; this coupling constant is larger than that (255 Hz) in II, but still smaller than that (676 Hz) in **Ib**. Although no tungsten satellites could be found for P(x), the signal for P(b) exhibited an unusually large three-bond coupling to tungsten $({}^{3}J_{WP(b)} = 150.8$ Hz), most likely because of the enhanced coupling between P(x) and P(b).

X-ray Crystal Structure of Cl(Et₃P)₂Pt[\mu-\eta¹,\eta¹,\eta², C=**P**{**W(CO)**₅}]**Pt(PEt₃)₂ (IV).** A thermal ellipsoid drawing of **IV** (Figure 2) shows that the complex contains a W(CO)₅ fragment attached to the C=**P** phosphorus atom and has many structural features in common with the X-ray-determined structure of complex **II**.⁹ Both of the platinum atoms in **IV** are in planar environments; the sum of angles around Pt(1) as defined by C(1), P(2), P(3), and Cl(1) is 360.1°, while the sum of angles around Pt(2) as defined by C(1), P(4), and P(5) is 360.4°. The C(1)–P(1) distance (1.663(9) Å) in

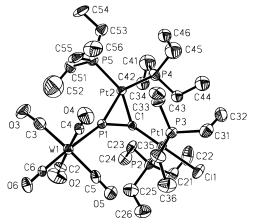

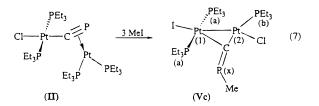

Figure 2. Thermal ellipsoid drawing of $Cl(Et_3P)_2Pt[\mu-\eta^1,\eta^1,\eta^2-C\equiv P\{W(CO)_5\}]Pt(PEt_3)_2$ (**IV**).

IV is the same within error as that (1.666(6) Å) in **II**, indicating that coordination of the W(CO)₅ unit has not dramatically changed the character of the cyaphide C-P bond. This distance is similar to a C-P double-bond distance (e.g., 1.67 Å in Ph(H)C=PMes*)²⁰ and to the C–P distance (1.67(2) Å) in the η^2 -phosphaalkyne complex $[Pt(PPh_3)_2(\eta^2-t-BuC \equiv P)]^{21}$ and is consistent with back-bonding from Pt(2) into the π^* orbital of the C≡P bond, affording some metallaphosphacyclopropene character in this three-atom unit in IV. The Pt(1)-C(1)-P(1) angle $(145.2(6)^{\circ})$ is similar to that in **II** $(144.0(3)^{\circ})$, and the W(1)-P(1)-C(1) angle $(136.1(3)^{\circ})$ is also bent, indicating that P(1) is close to sp^2 hybridization. This is also evident from the sum of the angles (355.3°) around P(1) involving W(1), Pt(2), and C(1), which indicates that P(1) is nearly planar. The W(1)-P(1) distance (2.531(3) Å) is very similar to the W-P bond length (2.539(3) Å) in the bridging phosphaalkyne complex $Mo_2(CO)_4(Cp)_2$ {t-BuCP[W(CO)₅]}²² and is slightly longer than typical W-P distances in structurally characterized W(CO)₄(PR₃)₂ complexes (e.g., 2.502 Å in *cis*-W(CO)₄(PMe₃)₂).²³ The Pt(2)–C(1) distance (2.104(9) Å) in **IV** is the same within experimental error as the corresponding distance (2.083(5) Å) in **II**, and the Pt(1)-C(1) distances (1.952(9) Å in **IV** and 1.950(6) Å in **II**) are also the same within error. However, the Pt(2)-P(1) distance (2.292(3) Å) in **IV** is shorter than the corresponding distance (2.337(2) Å) in II.

Alkylation Reactions of Cl(Et₃P)₂Pt(μ - η^1, η^2 -C= P)Pt(PEt₃)₂ (II). The reaction (eq 7) of 3 equiv of MeI with Cl(Et₃P)₂Pt(μ - η^1, η^2 -C=P)Pt(PEt₃)₂ (II) in THF for 12 h at 25 °C results in the formation of the methyl isocyaphide complex (Cl)(Et₃P)Pt(μ -C=PMe)Pt(PEt₃)₂(I) (Vc) with concomitant formation of the phosphonium salt (MePEt₃)⁺ I⁻. This reaction entails the conversion of a cyaphide (C=P)⁻ ligand to an isocyaphide (C=PMe) ligand and substitution of a coordinated PEt₃ ligand (lost as (MePEt₃)⁺ I⁻) with an iodide ligand; thus, the MeI acts both as a methylating agent and as a phosphine scavenger. Although complex Vc is stable in THF solution at room temperature for several weeks, suitable

crystals could not be obtained for an X-ray diffraction study as the compound only forms an oil. However, the complex is likely isostructural with the previously obtained semibridging isocyaphide complex (Cl)(Et₃P)- $Pt(\mu-C=PMes^*)Pt(PEt_3)_2(Cl)$ (2)⁹ on the basis of its ³¹P NMR spectrum (Table 2) and the ¹³C-³¹P coupling constants obtained from the use of ¹³C-labeled MeI in this reaction. Thus, the η^1, η^2 -cyaphide ligand in **II** is converted to a semibridging isocyaphide ligand in Vc with the formation of a Pt-Pt bond. This reaction has some precedent in related isocyanide chemistry, as the conversion of coordinated cyanide $(C \equiv N)^-$ ligands to isocyanide (C≡NR) ligands with various alkylating agents is a well-known synthetic route to isocyanide complexes, although these reactions have been carried out only on terminal cyanide complexes.²⁴ This new synthetic route to an isocyaphide complex is much different than the reaction (eq 1) of the phosphavinyl complex *trans*-Cl(Et₃P)₂Pt[C(Cl)=PMes*] (1) with Pt-(PEt₃)₄ to generate the semibridging isocyaphide complex (Cl)(Et₃P)Pt(μ -C=PMes*)Pt(PEt₃)₂(Cl) (2)⁹ or the reactions (eq 2) of $[Cp_2(CO)_2Fe_2(\mu-CO)(\mu-CSMe)]^+$ with RP(H)(SiMe₃) and DBU to generate the bridging isocyaphide complexes $[Cp_2(CO)_2Fe_2(\mu-CO)(\mu-C=PR)]$ (3);⁷ both of these syntheses were limited by the use of bulky aryl R-groups on the C≡PR phosphorus atom. In contrast, the reaction of II with MeI allows for the formation of an isocyaphide with a sterically small methyl group and could conceivably be a more general route to diplatinum isocyaphide complexes. To test this, the reaction in eq 7 was attempted with several different alkyl and aryl halides (e.g., benzyl bromide, isopropyl iodide, allyl bromide, o-iodo toluene, and 2,4,6-tri-tertbutylbenzyl bromide) under the same reaction conditions and stoichiometry as in the MeI reaction. The reactions of both benzyl bromide (BnBr) and isopropyl iodide (i-PrI) with II afforded similar isocyaphide products, $(Cl)(Et_3P)Pt(\mu-C=PBn)Pt(PEt_3)_2(Br)$ (VI) and (Cl)(Et₃P)Pt(μ -C=P*i*-Pr)Pt(PEt₃)₂(I) (VII), respectively, as evidenced by ³¹P NMR spectroscopy (see Table 2). However, the benzyl derivative could not be separated from impurities that were present, and the i-Pr derivative was unstable and decomposed before the reaction was complete. The reaction of allyl bromide with II formed completely different products that could not be isolated, while the aryl halides did not react with compound II, even after stirring for several days at room temperature.

Complex Vc was characterized by electrospray mass spectrometry and ³¹P, ³¹P{¹H}, and ¹³C{¹H} NMR spectroscopy. The ³¹P NMR spectrum of complex Vc shows chemical shifts and coupling constants (Table 2) very similar to those measured in the semibridging isocyaphide complex (Cl)(Et₃P)Pt(μ -C=PMes*)Pt(PEt₃)₂(Cl) (2)⁹ and is thus proposed to have the same structure.

^a See eq 7 for atom labels.

The ³¹P NMR spectrum of Vc exhibits three different signals. The peak at δ 155.4 ppm, assigned to P(x), is split into a doublet of triplets with two different ¹⁹⁵Pt satellites, indicative of the unsymmetrical, semibridging bonding mode of the C≡PMe ligand. The doublet $({}^{2}J_{P(x)P(b)} = 15.3 \text{ Hz})$ arises from coupling to the single PEt₃ ligand (P(b)) on Pt(2), while the triplet $({}^{3}J_{P(x)P(a)} =$ 12.1 Hz) results from coupling to the two equiv PEt₃ ligands (P(a)) on Pt(1). The larger coupling constant to platinum (${}^{2}J_{Pt(2)P(x)} = 564.7$ Hz) is assigned to coupling with the four-coordinate platinum Pt(2), while the smaller Pt–P coupling constant (${}^{2}J_{Pt(1)P(x)} = 231.9$ Hz) is assigned to coupling with the five-coordinate platinum atom Pt(1); these assignments are made on the basis of the assignments in compound **2** and by the larger J_{PtP} coupling constants that are typically found in platinum complexes with lower coordination numbers.²⁵ From these $J_{\rm PP}$ coupling constants, the signal at δ 8.7 ppm is assigned to P(a), while the signal at δ 21.52 is assigned to P(b). Because the signal for P(a) is farther upfield than the analogous peak in 2, while the peaks for P(b) in Vc and 2 have quite similar chemical shifts, it is assumed that the iodide ligand in Vc is on the platinum (Pt(1)) that contains two PEt₃ groups (P(a)). One aspect of the ³¹P NMR spectrum of Vc that supports its structural assignment as being similar to that of 2 is the large difference in the one-bond J_{PtP} coupling constants in the signals for P(a) and P(b); for P(a) in **Vc**, the value of ${}^{1}J_{Pt(1)P(a)} = 2338.9$ Hz is similar to those found in *trans*-Pt(PEt₃)₂X₂ complexes;²⁵ while for P(b), the value of ${}^{1}J_{Pt(2)P(b)} = 5173.7$ Hz is very large and more similar to those found in three-coordinate Pt(0) complexes.²⁵ This difference in the J_{PtP} coupling constants is greater in Vc than in compound 2 and has been discussed previously in the analogous semibridging carbonyl complex (Cl)(Ph₃P)Pt(µ-CO)Pt(PPh₃)₂(Cl) (4), which is very similar in structure to Vc and 2, but with PPh₃ instead of PEt₃ ligands and a semibridging CO ligand in place of the C = PR ligands.^{26,27} Complex 4 exhibits a value of ${}^{1}J_{PtP} = 2680$ Hz for the two equiv PPh₃ groups (P(a)) on the five-coordinate platinum and a value of ${}^{1}J_{PtP} = 5440$ Hz for the PPh₃ group (P(b)) on the four-coordinate platinum (see Table 2 for further comparisons). This difference was rationalized by suggesting some degree of mixed valence character between the two platinum atoms.²⁶ To further verify that the methyl group is attached to the phosphorus atom in complex Vc, the reaction (eq 7) was carried out using

Scheme 1

¹³C-labeled MeI. The ³¹P NMR spectrum of labeled Vc exhibited an extra doublet in the signal for P(x) from coupling to the labeled methyl group with ${}^{1}J_{P(x)C} = 48.9$ Hz. This value is similar to the value of ${}^{1}J_{PC} = 51.1$ Hz found in the phosphonium salt (MePEt₃)⁺ I⁻ product of this reaction. Interestingly, the signal for P(b) also exhibited a small coupling $({}^{4}J_{P(x)C} = 10.6 \text{ Hz})$ to the methyl group. The ¹³C NMR signal for the methyl group at δ 10.5 was split into a doublet of doublets by P(x) and P(b). This peak also exhibited a small Pt-C coupling constant of ${}^{3}J_{PtC} = 51.2$ Hz, which is most likely a coupling with Pt(2), which is bonded more strongly to the C≡PR group. The ³¹P NMR spectra of complexes VI and VII (Table 2) are quite similar to those of Vc, and these compounds are proposed to be of similar structure. These spectroscopic results, along with comparisons with those of compounds 2 and 4, strongly suggest that complexes Vc, VI, and VII contain semibridging isocyaphide ligands.

Mechanistic Studies of the Formation of (Cl)-(Et₃P)Pt(µ-C=PMe)Pt(PEt₃)₂(I) (Vc). A likely pathway (Scheme 1) for the formation of complex Vc from complex II is the initial methylation of the $C \equiv P$ phosphorus atom to generate a cationic η^1, η^2 -isocyaphide intermediate (Va). The iodide anion then attacks at Pt(2) to generate the bridging isocyaphide intermediate Vb, which loses a PEt₃ group and forms a metal-metal bond to generate the product Vc. An intermediate similar to Vb was postulated in the reaction (eq 1) of the phosphavinyl complex trans- $Cl(Et_3P)_2Pt[C(Cl)=PMes^*]$ (1) with $Pt(PEt_3)_4$ to generate the semibridging isocyaphide complex (Cl)(Et₃P)Pt- $(\mu$ -C=PMes*)Pt(PEt₃)₂(Cl) (2).⁹ In an attempt to verify this pathway by isolation of the cationic η^1, η^2 -isocyaphide intermediate (Va), complex II was reacted with 1 equiv of MeI in the presence of 2 equiv of NaBPh₄ in THF at room temperature. The color of the solution turned to a very deep ruby red color after 1 h, and a ³¹P NMR spectrum (see below) showed a new complex that matches the structure drawn for Va where the iodide anion has been replaced with (BPh₄⁻). This complex was then isolated in reasonably pure form by filtering the solution and adding hexanes to form an oil of mainly

Va. When a 10-fold excess of NaI was added to a solution of Va in THF, the color changed from deep red to light orange in 10 min, and a ³¹P NMR spectrum showed that this complex was completely converted to the semibridging isocyaphide complex Vc, which strongly suggests that Va is an intermediate that forms before Vc in the reaction of MeI with complex II. In a separate experiment, complex **II** was reacted with MeO₃SCF₃ in THF; the color turned to deep red within a few minutes, and a ³¹P NMR spectrum of the solution again showed complex Va where a triflate anion is substituted for the iodide anion. Reaction of this solution with a 10-fold excess of NaI afforded complex Vc, providing further evidence for the pathway outlined in Scheme 1. Although there was no evidence in the ³¹P NMR spectra for other intermediates, Vb is a likely intermediate that explains the rearrangement of the η^1, η^2 -isocyaphide ligand in **Va** to the semibridging isocyaphide ligand in Vc. In contrast to Vc, which contains a Pt-Pt bond, the ³¹P NMR spectrum (see below) of Va suggests that there is no Pt-Pt bond in this cationic isocyaphide complex. Clearly, compound Va does not contain a semibridging isocyaphide similar to that in Vc, and it is not clear why substitution of a PEt₃ group in Va by an iodide anion causes this rearrangement to take place. Complex **Va** is the first to exhibit an η^1, η^2 -bridging isocyaphide ligand.

Although complex Va could not be isolated in pure form, the ³¹P NMR spectrum is characteristic of an η^1, η^2 bridging isocyaphide structure and shows features (Table 1) very similar to those in the spectra of the η^1, η^1, η^2 -bridging trimetallic cyaphide complexes with a $Pt(Cl)_2(PEt_3)$ fragment (III) and a $W(CO)_5$ fragment (IV) on the cyaphide phosphorus atom. The signal at δ 34.7 ppm in **Va**, assigned to P(x), is shifted 120 ppm upfield from the corresponding P(x) peak in Vc; this shift is most consistent with an η^1, η^2 -bridged species. The chemical shift is quite similar to that (δ 41.4 ppm) in the tungsten-coordinated cyaphide complex IV, which differs only in that it is neutral and contains a W(CO)₅ group in place of the Me group on Va. Also supporting the proposed structure is the fact that the splitting patterns and coupling constants in Va, III, and IV are all quite similar (Table 1). The coupling constants between P(x) and the PEt₃ groups again are larger than those in the η^1, η^2 -cyaphide complex **(II)**, with the most dramatic effect again being a large coupling $({}^{2}J_{P(x)P(b)} =$ 148.9 Hz) between P(x) and P(b). This is very similar to the ${}^{2}J_{P(x)P(b)}$ values found in **III** (${}^{2}J_{P(x)P(b)} = 148.0$ Hz) and **IV** (${}^{2}J_{P(x)P(b)} = 152.9$ Hz). The ${}^{195}Pt - {}^{31}P$ coupling constants found in Va are also similar to those found in III and IV (Table 1) and provide further evidence for the proposed structure. Since there is no $^{195}\mathrm{Pt}-^{31}\mathrm{P}$ coupling of P(a) with Pt(2) or between P(b) and P(c) with Pt(1), the existence of a Pt–Pt bond in **Va** is doubtful; in Vc and 2, which contain Pt-Pt bonds, these couplings to the platinum atom of the adjacent metal fragment were significant (43-512 Hz). To further verify that the methyl group is attached to the cyaphide phosphorus atom, complex Va was prepared by reacting complex II with ¹³C-labeled MeI in the presence of NaBPh₄. The ³¹P NMR spectrum of this labeled complex exhibited additional doublets [P(x) (${}^{1}J_{P(x)C} = 71.5 \text{ Hz}$), P(b) (${}^{3}J_{P(b)C}$ = 8.4 Hz) and P(c) $({}^{3}J_{P(c)C} = 12.6$ Hz)] as a result of

coupling to the labeled methyl group. The ^{13}C NMR spectrum also displayed a peak for the methyl group at δ 8.7 ppm that was split into a doublet of doublet of doublets by these three phosphorus atoms. These results are entirely consistent with the proposed structure of **Va** and indicate that the attachment of a W(CO)₅, Pt(Cl)₂(PEt₃), or Me⁺ group to the cyaphide phosphorus atom in complex **II** gives products with very similar ³¹P NMR spectra and structures.

Summary

The new structurally characterized, phosphavinyl complex trans-Cl(Et₃P)₂Pt[C(Cl)=PN(SiMe₃)₂] (**Ib**) reacts (eq 5) with Pt(PEt₃)₂Cl₂ and Na/benzophenone ketyl to form the known η^1 , η^2 -bridged cyaphide complex Cl- $(Et_3P)_2Pt(\mu-\eta^1,\eta^2-C=P)Pt(PEt_3)_2$ (II) but this route is much simpler and gives higher yields than previously reported (eq 3).⁹ Lewis acid adducts at the electron pair on the phosphorus of the cyaphide $(C \equiv P)^{-}$ ligand in complex II are obtained by reaction with 0.5 equiv of [Pt(Cl)₂(PEt₃)]₂ or with 1 equiv of W(CO)₅(THF) to generate (eq 6) the first examples of trinuclear metal cyaphide complexes $Cl(Et_3P)_2Pt[\mu-\eta^1, \eta^1,\eta^2-C=P{Pt (PEt_3)(Cl)_2$]Pt $(PEt_3)_2$ (III) and $Cl(Et_3P)_2$ Pt $[\mu-\eta^1,\eta^1,\eta^2-\eta^2]$ $C = P\{W(CO)_5\} Pt(PEt_3)_2$ (IV), respectively. The phosphorus of the cyaphide $(C \equiv P)^{-}$ ligand in complex II is also alkylated (eq 7) by MeI to give the semibridging methyl isocyaphide (C=PMe) complex (Cl)(Et₃P)Pt(μ - $C=PMe)Pt(PEt_3)_2(I)$ (Vc). This transformation (Scheme 1) was demonstrated to involve a cationic η^1 , η^2 -bridging isocyaphide intermediate [(Cl)(Et₃P)₂Pt(μ - η^1 , η^2 -C=PMe)- $Pt(PEt_3)_2$ (I) (Va), which was isolated as the triflate salt when complex II was reacted with MeO₃SCF₃. The μ - η^1 , η^2 -C=PMe ligand in compound **Va** represents a new bonding mode for isocyaphide ligands, and the methylation reaction of compound II to form Vc provides a new method of forming semibridging isocyaphide complexes. Compound Vc is also the first example of a complex to contain an isocyaphide ligand with a nonbulky alkyl group, demonstrating that steric protection of the reactive C≡P bond by bulky R-groups is not necessary for the stabilization of transition metal-coordinated isocyaphide ligands.

Experimental Section

General Procedure. All manipulations were carried out under a dry, oxygen-free argon atmosphere, using standard Schlenk techniques. All solvents employed were reagent grade and dried by refluxing over appropriate drying agents under nitrogen. Tetrahydrofuran (THF) and diethyl ether (Et₂O) were distilled over sodium benzophenone ketyl, while hexanes and dichloromethane (CH₂Cl₂) were distilled over CaH₂.

The ³¹P{¹H} and ³¹P NMR spectra were recorded on a Bruker AC 200 MHz spectrometer using 85% H₃PO₄ (δ 0.00 ppm) as the external standard. The ¹³C{¹H} and ¹³C NMR spectra were recorded on a Bruker DRX 400 MHz spectrometer using CDCl₃ as the internal standard. Electrospray mass spectra were recorded on a Finnigan TSQ 700 spectrometer using CH₂Cl₂ as solvent. Elemental analyses were performed by National Chemical Consulting, Inc., Tenafly, NJ. The compounds Pt(PEt₃)₄,²⁸ Cl₂C=PN(SiMe₃)₂,²⁹ [Pt(Cl)₂(PEt₃)]₂,³⁰ Pt(PR₃)₂Cl₂,³¹ and Na/benzophenone ketyl were prepared by

⁽²⁸⁾ Yoshida, T.; Matsuda, T.; Otsuka, S. Inorg. Synth. 1979, 19, 110.

literature methods. Phosphine ligands were purchased from Strem and used without further purification, with the exception of PPh₃, which was recrystallized from MeOH. Methyl iodide (MeI) and methyl triflate (MeO₃SCF₃) were purchased from Aldrich and used without further purification. W(CO)₅-(THF) was prepared by photolysis of W(CO)₆ in THF for 6 h at 20 °C.³²

Preparation of *trans*-Cl(Et₃P)₂Pt[C(Cl)=PN(SiMe₃)₂] (Ib) through Intermediate cis-Cl(Et₃P)₂Pt[C(Cl)=PN- $(SiMe_3)_2$] (Ia). To a cooled (-50 °C) solution of Pt(PEt₃)₄ (1.50 g, 2.25 mmol) in hexanes (20 mL) was added Cl₂C=PN(SiMe₃)₂ (0.616 g, 2.25 mmol). A ${}^{31}P{}^{1}H{}$ NMR spectrum taken 10 min after the addition (-50 °C) showed complete conversion to Ia. After the solution had warmed to 0 °C over the course of 30 min, a ³¹P{¹H} NMR spectrum showed that compound Ia had completely isomerized to Ib. The almost colorless solution was warmed to room temperature over the course of 10 min. and the solvent was removed under vacuum. The residue was treated with 20 mL of hexanes and filtered, and the filtrate was concentrated to 10 mL. A white precipitate formed, which was found to be Pt(PEt₃)₂Cl₂ by comparison of its ³¹P NMR spectrum with that of an authentic sample. The precipitate was filtered off, and the filtrate was concentrated to 5 mL under vacuum. The light orange/brown solution was cooled slowly to -78 °C for 3 days, after which time large, light yellow crystals had formed. The crystals were isolated by cannulating off the mother liquor, washing with 2 \times 5 mL portions of hexanes at -78 °C, and drying under vacuum to give air-stable Ib (1.24 g, 78%). $^{31}P\{^{1}H\}$ NMR (hexanes) (see eq 4 for atom labels) for Ia, -50 °C: $\delta(P(x))$ 225.1 (dd, ${}^{3}J_{P(x)P(b)} = 33.0$ Hz, ${}^{3}J_{P(x)P(a)} = 8.3$ Hz, ${}^{2}J_{PtP(x)} = 410.0$ Hz), $\delta(P(b))$ 10.1 (dd, ${}^{3}J_{P(b)P(x)}$ = 33.0 Hz, ${}^{2}J_{P(b)P(a)}$ = 16.2 Hz, ${}^{1}J_{PtP(b)}$ = 1908 Hz), $\delta(P(a))$ 5.6 (dd, ${}^{2}J_{P(a)P(b)} = 16.2$ Hz, ${}^{3}J_{P(a)P(x)} = 8.3$ Hz, ${}^{1}J_{PtP(a)} = 3874$ Hz). For **Ib**, 25 °C: $\delta(P(x))$ 222.3 (t, ${}^{3}J_{P(x)P(a)} = 20.0$ Hz, ${}^{2}J_{PtP(x)} =$ 676.0 Hz), $\delta(P(a))$ 14.1 (d, ${}^{3}J_{P(a)P(x)} = 20.0$ Hz, ${}^{1}J_{PtP(a)} = 2680$ Hz). Electrospray MS (for Ib): m/e 705 (M⁺). Anal. Calcd for $C_{19}H_{48}Cl_2N_1P_3Pt_1Si_2$ (Ib): C, 32.34; H, 6.86; N, 1.98. Found: C, 31.25; H, 6.62; N, 1.87. Although the carbon analyses were consistently low for repeated analyses of Ib, the composition of the compound is strongly supported by the NMR and mass spectra, as well as the X-ray diffraction study.

Preparation of Cl(Et₃P)₂Pt(μ - η^1 , η^2 -C=P)Pt(PEt₃)₂ (II). To a dry mixture of *trans*-Cl(Et₃P)₂Pt[C(Cl)=PN(SiMe₃)₂] (Ib) (1.00 g, 1.42 mmol) and Pt(PEt₃)₂Cl₂ (0.747 g, 1.49 mmol) at room temperature was added dropwise with stirring 20.8 mL of a solution of 0.204 M Na/benzophenone ketyl in THF (4.25 mmol) (the molarity of the Na/benzophenone solution was determined by quenching a measured amount with water and titrating with standardized HCl solution). The addition was done at a rate that was determined by the color change; as the color turned blue, addition was halted until the color changed back to orange. The total time of the addition was ca. 45 min, after which time the color of the solution was dark red with a large amount of NaCl precipitate. The solution was filtered through Celite, and the solvent was removed from the filtrate under vacuum. Extended drying under vacuum, especially with heating, was found to cause decomposition. The dark red residue was treated with hexanes (30 mL), the mixture was filtered through Celite, and the filtrate was reduced in volume to 10 mL. A ³¹P NMR spectrum of this solution showed II; benzophenone was present as the only impurity. The solution was cooled slowly to -78 °C and kept at this temperature for 1 week, after which time dark red crystals of II had formed. The crystals were isolated by cannulating off the mother liquor, washing with 2 imes 5 mL

portions of hexanes at -78 °C, and drying under vacuum to give **II** (1.05 g, 79%). Compound **II** was characterized by comparison of its ³¹P NMR spectrum with that of an authentic sample. ³¹P{¹H} NMR (THF) (see eq 5 for atom labels): $\delta(P(x))$ 107.0 (ddt, ²*J*_{P(x)P(b)} = 13.7 Hz, ²*J*_{P(x)P(c)} = 10.7 Hz, ³*J*_{P(x)P(a)} = 10.7 Hz, ²*J*_{P(1)P(x)} = 255 Hz, ¹*J*_{P(2)P(x)} = 58 Hz), $\delta(P(c))$ 18.6 (dd, ²*J*_{P(c)P(b)} = 35.1 Hz, ²*J*_{P(c)P(x)} = 10.7 Hz, ¹*J*_{Pt(2)P(c)} = 3619 Hz, ³*J*_{P(1)P(c)} = 137 Hz), $\delta(P(b))$ 15.0 (ddt, ²*J*_{P(b)P(c)} = 35.1 Hz, ²*J*_{P(b)P(x)} = 13.7 Hz, ⁴*J*_{P(b)P(a)} = 4.5 Hz, ¹*J*_{Pt(2)P(b)} = 3155 Hz), $\delta(P(a))$ 4.9 (dd, ³*J*_{P(a)P(x)} = 10.7 Hz, ²*J*_{P(a)P(b)} = 4.5 Hz, ¹*J*_{Pt(1)P(a)} = 2936 Hz).

Preparation of Cl(Et₃P)₂**Pt**[μ - η ¹, η ¹, η ²-C=**P**{**Pt(PEt₃)**-(Cl)₂}]Pt(PEt₃)₂ (III). To a dry mixture of Cl(Et₃P)₂Pt(μ - η^1 , η^2 - $C = P)Pt(PEt_3)_2$ (II) (0.100 g, 0.106 mmol) and $[Pt(Cl)_2(PEt_3)]_2$ (0.0408 g, 0.0531 mmol) at room temperature was added 10 mL of THF with stirring. The color turned from dark orange to light orange immediately. A ³¹P NMR spectrum taken after 5 min of stirring showed quantitative formation of III, with a small amount of Pt(PEt₃)₂Cl₂ present (characterized by comparison of its ³¹P NMR spectrum with that of an authentic sample). The volume of the solvent was reduced to 2 mL, and 5 mL of hexanes was added to precipitate the Pt(PEt₃)₂Cl₂ impurity. The solution was filtered, and a ³¹P NMR spectrum of the filtrate showed very pure III. Compound III is stable in hexanes for several days at -30 °C, but decomposes at room temperature in about 1 day. Compound III could not be purified for elemental analysis, as it decomposed to unidentified products under vacuum, and was characterized by ³¹P NMR spectroscopy. ³¹P{¹H} NMR (THF) (see eq 6 for atom labels): $\delta(P(x))$ 111.2 (dddt, ${}^{2}J_{P(x)P(d)} = 472.3$ Hz, ${}^{2}J_{P(x)P(b)} =$ 148.0 Hz, ${}^{2}J_{P(x)P(c)} = 42.5$ Hz, ${}^{3}J_{P(x)P(a)} = 21.4$ Hz), $\delta(P(c))$ 17.2 (ddd, ${}^{2}J_{P(c)P(x)} = 42.5$ Hz, ${}^{4}J_{P(c)P(d)} = 22.0$ Hz, ${}^{2}J_{P(c)P(b)} = 8.7$ Hz, ${}^{1}J_{\text{Pt}(2)\text{P(c)}} = 2926$ Hz), $\delta(\text{P(b)})$ 15.9 (ddd, ${}^{2}J_{\text{P(b)P(x)}} = 148.0$ Hz, ${}^{4}J_{P(b)P(d)} = 56.0$ Hz, ${}^{2}J_{P(b)P(c)} = 8.7$ Hz, ${}^{1}J_{Pt(2)P(b)} = 3601$ Hz), $\delta(P(d))$ 5.21 (ddd, ${}^{2}J_{P(d)P(x)} = 472.3$ Hz, ${}^{4}J_{P(d)P(b)} = 56.0$ Hz, ${}^{4}J_{P(d)P(c)} = 22.0$ Hz, ${}^{1}J_{Pt(3)P(d)} = 3020$ Hz), $\delta(P(a))$ 5.0 (d, ${}^{3}J_{P(a)P(x)}$ = 21.4 Hz, ${}^{1}J_{Pt(1)P(a)}$ = 2829 Hz). (The ${}^{195}Pt-{}^{31}P$ coupling constants in the P(x) signal were not possible to determine because of the complexity of the splittings.)

Preparation of Cl(Et₃P)₂**Pt**[μ - η ¹, η ¹, η ²-**C**=**P**{**W(CO)**₅}]**Pt**-(**PEt₃**)₂ (**IV**). To a solution of $Cl(Et_3P)_2Pt(\mu-\eta^1,\eta^2-C\equiv P)Pt$ -(PEt₃)₂ (II) (0.500 g, 0.531 mmol) in THF (10 mL) at room temperature was added W(CO)₅(THF) (0.531 mmol) in THF (20 mL) with stirring. The color of the solution turned from dark orange to dark red after 1 h of stirring. The solvent volume was reduced to ca. 3 mL under vacuum, and 15 mL of hexanes was added. The flask was cooled to -30 °C for 1 h with formation of an oily solid impurity. The solution was filtered, and the filtrate was reduced in volume to 5 mL and then cooled slowly to -78 °C for 3 days, after which time light orange crystals of IV had formed. The crystals were isolated by cannulating off the mother liquor, washing them with 2 imes5 mL portions of hexanes at -78 °C, and drying under vacuum at -50 °C to give IV (0.375 g, 56%) that was pure by ³¹P NMR spectroscopy. Further drying under vacuum at room temperature resulted in partial decomposition to an oily solid, which prevented proper elemental analysis. ³¹P{¹H} NMR (THF) (see eq 6 for atom labels): $\delta(P(x))$ 41.4 (ddt, ² $J_{P(x)P(b)} = 152.9$ Hz, ${}^{2}J_{P(x)P(c)} = 38.7 \text{ Hz}, {}^{3}J_{P(x)P(a)} = 18.9 \text{ Hz}, {}^{1}J_{P(t)P(x)} = 507 \text{ Hz},$ $\delta(P(c)) 13.9 (dd, {}^{2}J_{P(c)P(x)} = 38.7 \text{ Hz}, {}^{2}J_{P(c)P(b)} = 9.1 \text{ Hz}, {}^{1}J_{P(t2)P(c)}$ = 2917 Hz), δ (P(b)) 16.6 (dd, ${}^{2}J_{P(b)P(x)}$ = 152.9 Hz, ${}^{2}J_{P(b)P(c)}$ = 9.1 Hz, ${}^{3}J_{WP(b)} = 150.8$ Hz, ${}^{1}J_{Pt(2)P(b)} = 3568$ Hz), $\delta(P(a))$ 3.1 (d, ${}^{3}J_{P(a)P(x)} = 18.9$ Hz, ${}^{1}J_{Pt(1)P(a)} = 2818$ Hz).

Preparation of [(Cl)(Et₃P)Pt(μ -**C=PMe)Pt**(**PEt₃)₂(I)] (Vc).** To a stirred solution of Cl(Et₃P)₂Pt(μ - η , η ²-C=P)Pt-(PEt₃)₂ **(II)** (0.500 g, 0.531 mmol) in THF (10 mL) at room temperature was added MeI (0.226 g, 1.59 mmol) all at once. After stirring for 12 h at 25 °C, the color had changed from dark orange to light orange and a precipitate of [MePEt₃]I⁻ had formed (characterized by comparison of its ³¹P NMR with an authentic sample). The solution was filtered, the solvent was removed from the filtrate under vacuum, and the residue

was treated with 25 mL of hexanes. After reducing the solvent under vacuum to 5 mL, the solution was filtered and cooled slowly to -78 °C for 2 days to form an oil of **Vc** that was pure by ³¹P NMR spectroscopic studies (yield 0.386 g, 75%). A similar preparation was carried out using ¹³C-labeled MeI in order to obtain ¹³C-³¹P coupling constants. ³¹P{¹H} NMR (THF) (see eq 7 for atom labels): $\delta(P(x))$ 155.4 (dt, ³J_{P(x)P(b)} = 15.3 Hz, ³J_{P(x)P(a)} = 12.1 Hz, ²J_{Pt(2)P(x)} = 564.7 Hz, ²J_{Pt(1)P(x)} = 231.9 Hz), $\delta(P(b))$ 21.5 (d, ³J_{P(b)P(x)} = 15.3 Hz, ¹J_{P(t)(b)} = 463.4 Hz), $\delta(P(a))$ 8.7 (d, ³J_{P(a)P(x)} = 12.1 Hz, ¹J_{Pt(1)P(a)} = 2338.9 Hz, ²J_{Pt(2)P(a)} = 43.5 Hz). ¹³C{¹H} NMR (C₆D₆): $\delta(CH_3P)$ 10.5 (dd, ¹J_{CP(x)} = 48.9 Hz, ⁴J_{CP(b)} = 10.6 Hz, ³J_{CPt(2)} = 51.2 Hz). Electrospray MS (for **Vc**): *m/e* 963 (M⁺ – H).

Formation of $[Cl(Et_3P)_2Pt(\mu-\eta^1,\eta^2-C\equiv PMe)Pt(PEt_3)_2]^+$ **(Va).** Method A. To a stirred solution of $Cl(Et_3P)_2Pt(\mu-\eta^1,\eta^2-\eta^2)$ C=P)Pt(PEt₃)₂ (II) (0.350 g, 0.372 mmol) in THF (15 mL) at room temperature was added MeO₃SCF₃ (0.0610 g, 0.372 mmol) all at once. After stirring for 5 min, the color of the solution changed from dark orange to dark, ruby red. The volume of the solution was reduced to 2 mL, and 15 mL hexanes was added to form a dark red oil that separated from solution. The remaining light red solution was removed from the oil with a cannula, and the oil was washed with 3×8 mL portions of hexanes to afford the triflate salt of Va (crude yield 0.279 g, 68%). A 31 P NMR spectrum showed that this oil contained a small amount of impurities, which were more prevalent after 1 day. Complete decomposition was evident after 1 week at room temperature. (The ³¹P NMR spectrum was the same as that for the BPh₄⁻ salt below.)

Method B. To a stirred solution of $Cl(Et_3P)_2Pt(\mu-\eta^1,\eta^2-C \equiv P)Pt(PEt_3)_2$ **(II)** (0.200 g, 0.212 mmol) and NaBPh₄ (0.145 g, 0.425 mmol) in THF (10 mL) at room temperature was added MeI (0.302 g, 0.212 mmol) all at once. The color of the solution turned from dark orange to very dark red after 3 h of stirring. The solution was treated with 10 mL of hexanes, and a large amount of oily precipitate formed. The solution was filtered, and the solvent in the filtrate was removed under vacuum. The residue was dissolved in 2 mL of THF, and 15 mL of hexanes was added to form a dark red oil that separated from the solution. The oil was isolated by cannulating off the solution and washing with 3×8 mL portions of hexanes

followed by 3 × 5 mL portions of Et₂O to afford the BPh₄⁻ salt of **Va** (crude yield 0.103 g, 38%). A similar preparation was carried out using ¹³C-labeled MeI in order to obtain ¹³C-³¹P coupling constants. ³¹P{¹H} NMR (THF) (see Scheme 1 for atom labels): $\delta(P(x))$ 34.7 (ddt, ² $J_{P(x)P(b)} = 148.9$ Hz, ² $J_{P(x)P(c)} = 23.8$ Hz, ³ $J_{P(x)P(a)} = 20.6$ Hz), $\delta(P(c))$ 20.1 (dd, ² $J_{P(c)P(x)} = 23.8$ Hz, ³ $J_{P(c)P(b)} = 10.2$ Hz, ¹ $J_{Pt(2)P(c)} = 2441$ Hz), $\delta(P(b))$ 18.7 (ddt, ² $J_{P(b)P(a)} = 3640$ Hz), $\delta(P(a))$ 8.1 (dd, ³ $J_{P(a)P(x)} = 20.6$ Hz, ⁴ $J_{P(a)P(b)} = 5.7$ Hz, ¹ $J_{Pt(1)P(a)} = 2661$ Hz). (The ¹⁹⁵Pt-³¹P coupling constants in the P(x) signal were not possible to determine because of the complexity of the splittings). ¹³C{¹H} NMR (THF): $\delta(CH_3P)$ 8.7 (ddd, ¹ $J_{CP(x)} = 71.5$ Hz, ³ $J_{CP(c)} = 12.6$ Hz, ³ $J_{CP(b)} = 8.4$ Hz).

Conversion of $[Cl(Et_3P)_2Pt(\mu-\eta^1,\eta^2-C=PMe)Pt(PEt_3)_2]^+$ (Va) to $[(Cl)(Et_3P)Pt(\mu-C=PMe)Pt(PEt_3)_2(I)]$ (Vc). To a stirred solution of Va (0.100 g, 0.0784 mmol) in THF (20 mL) at room temperature, prepared as in method B above, was added NaI (0.118 g, 0.784 mmol) as a solid. After stirring for 10 min, the color had changed from dark red to light orange. The solvent was removed under vacuum, and the residue was taken up in 20 mL of hexanes. The solution was filtered over Celite, and the filtrate was shown to contain mainly Vc by a ³¹P NMR spectrum, but it could not be isolated pure, as it contained impurities that likely resulted from decomposition of Va before or during the reaction.

X-ray Crystallographic Study of *trans*-Cl(Et₃P)₂Pt-[C(Cl)=PN(SiMe₃)₂] (Ib). Diffraction-quality crystals of Ib were obtained by recrystallization from hexanes at -78 °C. Data collection and reduction information are given in Table 3. A light orange crystal of Ib was mounted on a glass fiber for data collection. Cell constants were determined from reflections found in a rotation photograph. High-angle cell constants were determined from a subset of intense reflections in the range $35.0-50.0^{\circ} 2\theta$. The data were corrected for Lorentz and polarization effects. A correction based on nonlinear decay in the three standard reflections was applied to the data. An absorption correction based on measured crystal faces was applied. The space group *Pbca* was unambiguously determined by systematic absences and intensity statistics.³³ A successful direct methods solution was calcu-

^{*a*} Numbers in parentheses are estimated standard deviations in the least significant digits.

lated which provided all non-hydrogen atoms from the E-map. All non-hydrogen atoms were refined with anisotropic displacement parameters. All hydrogen atoms were refined as riding atoms with C–H distances of 0.96 Å. The hydrogen atoms in methylene groups were refined with individual isotropic displacement parameters, while methyl hydrogen atoms were refined as groups. Selected bond distances and bond angles are given in Table 4.

X-ray Crystallographic Study of Cl(Et₃P)₂Pt[μ - η ¹, η ¹, η ²- $C = P\{W(CO)_5\} Pt(PEt_3)_2$ (IV). Diffraction-quality crystals were obtained by slow evaporation of an Et₂O solution of IV. Data collection and reduction information are given in Table 3. An orange crystal of IV was mounted on a glass fiber for data collection. An initial set of cell constants was calculated from reflections taken from three sets of 20 frames. Final cell constants were calculated from a set of 5625 strong reflections taken during the data collection. The space group $P2_1/n$ was unambiguously determined by systematic absences and intensity statistics.³³ A hemisphere-type data collection was employed in which a randomly oriented region of space was surveyed to the extent of 1.3 hemispheres to a resolution of 0.84 Å. Three major swaths of frames were collected with 0.30° steps in ω , providing a high degree of redundancy. A successful direct methods solution was calculated which provided most non-hydrogen atoms from the E-map. Several full-matrix least-squares difference Fourier cycles were performed which located the remainder of the non-hydrogen atoms. All non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atom positions were generated with ideal geometries and refined as riding, isotropic

atoms. One triethylphosphine group (P4) was disordered in a 0.50:0.50 ratio and required the use of 426 restraints. The P4 group is duplicated (P4') in order to make a separate group, both of which have the same parameters. These groups were refined isotropically with additional restraints, and the other triethylphosphine groups in the molecule were used to group the two partially occupied groups in SHELTXTL SAME restraints.³³ Selected bond distances and bond angles are given in Table 5.

Acknowledgment. We thank the donors of the Petroleum Research Fund (Grant 27360-AC3), administered by the American Chemical Society, and the National Science Foundation (Grant CHE-9414242) for support of this research.
