Abstract

Hydroboration of fluorinated styrenes with common hydroborating agents results in polymerization. However, regioselective hydroboration has been achieved by utilizing iodoborane-dimethyl sulfide. A series of fluorinated β -phenethyl alcohols and amines were synthesized via this methodology.

1. Introduction

Due to the similarity in size, fluorine has been used as a replacement for hydrogen in many biologically active organic molecules, for use in PET (Positron Emission Tomography) scanning as well as to examine its influence in the biochemistry of such molecules [1]. Fluorine substitution on 2-substituted-1-alkenes substantially modifies the regioselectivity in the transition-metal catalyzed [2] and uncatalyzed [3–5] hydroboration reaction. While the hydroboration-oxidation of 2,3,4,5,6-pentafluorostyrene with $\text{BH}_3\cdot\text{THF}$, $\text{BHCl}_2\cdot\text{SMe}_2$, BHBBr_2 , ChxBClH , catecholborane (CBH), pinacolborane (PBH) yields the Markovnikov product [2,3], CH_2BH , 9-BBN and Si_2BH provide the anti-Markovnikov product [4]. Hydroboration with ThxBH_2 provides equal amounts of Markovnikov and anti-Markovnikov products [4].

Herein we report a simple and highly regioselective hydroboration of fluoro-substituted styrenes (**1**) for the synthesis of β -fluoroaryl organoboranes (**2**), which were readily converted to the corresponding fluorinated primary alcohols (**3**) and primary amines (**4**) (Scheme 1).

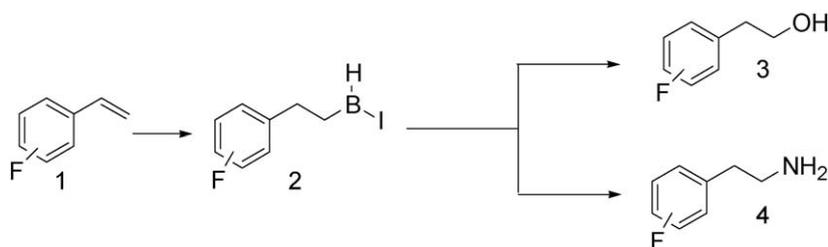

2. Results and discussion

The hydroboration-oxidation of 2-, 3-, and 4-fluorostyrenes under transition-metal catalyzed conditions provide the secondary alcohols (Scheme 2). In continuation of our research on the utilization of organoboranes for the synthesis of various fluorinated amino acids [6], we desired a simple, direct method for the selective access to the hydroboration products, which can be readily converted to the anti-Markovnikov alcohols as oxidation products. The preparation of Markovnikov alcohols from fluoro-substituted styrenes have been reported [7–13]. We expected the anti-Markovnikov products via the non-catalyzed (stoichiometric) hydroboration of fluoro-substituted styrenes with common hydroborating agents [14]. Our assumption was based on the fact that a lone fluorine atom on the benzene ring will have minimal electronic effect.

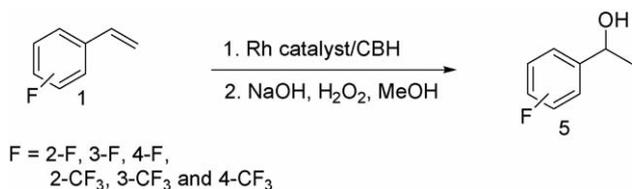

The initial hydroboration experiments were attempted on 2-fluorostyrene with $\text{BH}_3\cdot\text{SMe}_2$ in ethyl ether at 0 °C. To our surprise, the ^{11}B NMR of an aliquot of the reaction mixture showed a quartet (δ –20.3) corresponding to unreacted $\text{BH}_3\cdot\text{SMe}_2$. However, a TLC and ^1H NMR analysis revealed consumption of the olefin. Upon careful analysis, we observed that the attempted hydroboration had resulted in the polymerization of the olefin in the presence of borane, with the quantitative recovery of the borane reagent, as determined by hydrolysis [15]. The fluorostyrene met with the same fate in

the presence of several other boranes, such as BHCl₂·SMe₂, 9-BBN, BHCl₂, BH₂Cl and CHX₂BH. Hydroboration of 3-, 4-fluoro and 2-CF₃-, 3-CF₃- and 4-CF₃-styrenes also led to polymerization in the presence of BH₃·SMe₂, BH₃·THF, 9-BBN, BHCl₂, BH₂Cl and CHX₂BH (Scheme 3).

Our quest for a borane reagent that would not polymerize fluorostyrenes, led to the examination of BH₂I·Py or BH₂I·SMe₂. Vedejs and co-workers have recently reported the possibility of activating Py·BH₃ by replacing one of the hydrogens of borane with iodine and carrying out the hydroboration of alkenes and alkynes [16,17]. We applied the same technique for the hydroboration-oxidation of fluoro-substituted styrenes (Scheme 4). Thus, the hydroboration of 4-fluorostyrene with BH₂I·SMe₂, prepared via the iodination [18] of BH₃·SMe₂ in CS₂, was complete within 5 h at RT, as revealed by a doublet at δ -6.5 in the ¹¹B NMR spectrum. The reaction mixture was cooled to 0 °C, quenched with methanol and oxidized under alkaline

Table 1
Regioselective hydroboration-oxidation of fluoro-substituted styrenes^a

			1°-ol	2°-ol
1	2-F	96	3a (97)	5a (3)
2	3-F	92	3b (94)	5b (6)
3	4-F	95	3c (97)	5c (3)
4	2-CF ₃	82	3d (93)	5d (7)
5	3-CF ₃	80	3e (92)	5e (8)
6	4-CF ₃	92	3f (95)	5f (5)
7	2,3,4,5,6-F ₅	72	3g (33)	5g (67)

^a Reaction conditions: 1:1 ratio, BH₂I·SMe₂/fluorostyrene, RT, methanol (2 mL), 1.2 equiv. NaOH, 1.2 equiv. H₂O₂, 0 °C.

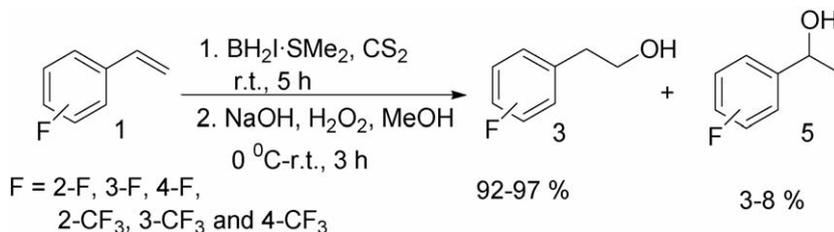

^b Isolated yields.

^c Isomer ratio determined by ¹H NMR.

conditions to obtain a 95 % yield of essentially pure primary alcohol product **3c** (**3c:5c** = 97:3).

This protocol was then applied to a variety of fluoro-substituted styrenes to provide the corresponding primary alcohols with high selectivity (Table 1). Interestingly, hydroboration of 2,3,4,5,6-pentafluorostyrene with BH₂I·SMe₂, followed by oxidation with alkaline H₂O₂ provided a 72% yield of a 33:67 mixture of primary and secondary alcohols (**3g** and **5g**) (Table 1, entry 7). This might be expected on the basis of our earlier results on the hydroboration of 2,3,4,5,6-pentafluorostyrene with ThxBH₂ [4].

Having succeeded in achieving the synthesis of the fluorinated β-phenethanols, we turned our attention to the preparation of representatives of the corresponding β-phenethyl amines [19–22]. Following hydroboration of 4-fluorostyrene

5.2.5. 3-(Trifluoromethyl)phenethyl alcohol (**3e**)

^1H NMR (300 MHz, CDCl_3): δ 7.61–7.30 (m, 4H), 3.87–3.83 (t, $J(\text{H,H}) = 6.42$ Hz, 2H), 2.98–2.82 (t, 2H), 2.22 (brs, 1H).

5.2.6. 4-(Trifluoromethyl)phenethyl alcohol (**3f**)

^1H NMR (300 MHz, CDCl_3): δ 7.59–7.43 (dd, 2H), 7.40–7.30 (dd, 2H), 3.91–3.86 (t, $J(\text{H,H}) = 6.34$ Hz, 2H), 2.99–2.90 (t, 2H), 1.75 (brs, 1H).

5.2.7. (\pm)- α -Methyl-2,3,4,5,6,-pentafluorobenzyl alcohol (**5g**)

^1H NMR (300 MHz, CDCl_3): δ 5.29–5.12 (s, 1H), 2.82 (brs, 1H), 1.69–1.52 (d, 3H). ^{19}F NMR (282 MHz, CDCl_3): δ –54.46 (t).

5.3. Hydroboration-amination of fluoro-substituted styrenes

An oven-dried, 50 mL round-bottomed flask, equipped with a side arm, was cooled to 0 °C under a stream of nitrogen. In the flask was placed CS_2 (10 mL) and $\text{BH}_3\cdot\text{SMe}_2$ (1.485 mL, 10.0–10.2 M, 15 mmol). The flask was maintained at 0 °C by immersion in an ice-water bath. To this flask was added a precooled I_2 solution (1.903 g, 7.5 mmol) in CS_2 (10 mL) slowly using a double-ended needle. After hydrogen evolution was completed, the solution was warmed to room temperature and 4-fluorostyrene (1.79 mL, 15 mmol) was added. After the completion of the reaction (5 h), monitored periodically by ^{11}B NMR doublet at δ –6.5, the reaction mixture was cooled to 0 °C with an ice bath, and quenched with methanol. To this boronic ester, solid hydroxylamine-*O*-sulfonic acid (3.392 g, 30 mmol) was added by using a solid addition tube. The reaction mixture was stirred at RT for 12 h to ensure complete conversion. Water (10 mL) and ethyl ether (15 mL) were added. The acidic aqueous layer was separated, cooled to 0 °C and layered with ethyl ether. The solution was then made strongly alkaline by adding aq. NaOH with stirring. The organic phase was separated and the combined organic phase was dried with Na_2SO_4 . Solvent was removed to afford **4a** (72%, **4a:6a** = 97:3).

5.3.1. 4-Fluorophenethyl amine (**4a**)

^1H NMR (300 MHz, CDCl_3): δ 7.22–6.84 (m, 4H), 2.89–2.60 (m, 4H), 1.16 (s, 2H).

5.3.2. 3-(Trifluoromethyl)phenethyl amine (**4b**)

^1H NMR (300 MHz, CDCl_3): δ 7.32–6.82 (m, 4H), 2.89–2.60 (m, 4H), 1.39 (s, 2H).
