(Received 14 June 1983. Revised 6 February 1984. Accepted 27 February 1984)

New cyclic juvenoids containing the 3,3-dimethylcyclohexane (esters 16, 18, 22, 26, and ethers $28 \mathbf{a}, \mathbf{b}$ ) or the 5,5-dimethyl-2-cyclohexene system (esters 15, 17, 21, 25, and ethers $27 \mathrm{a}, \mathrm{b}$ ) have been obtained by a several-step synthesis starting from dimedone (1). The compounds obtained exhibited morphogenetic activity against larvae of Dysdercus cingulatus and they were inactive on pupae of Tenebrio molitor.

## Introduction

One of the most important aims in studies on the effect of structural changes in analogs of insect juvenile hormones on their biological activities is to establish the "biologically active" conformation of juvenoids and thereby to estimate the shape of their biological receptor. It seems that comparative studies of biological activities of aliphatic juvenoids and their cyclic analogs could be very helpful for the solution of this problem. The activities of the latter compounds can be, in fact, ascribed only to
these conformations of aliphatic juvenoids which are forced by the presence of the cyclic system in the isoprenoid chain. Carrying out comparative studies of this type, we have synthesized cyclic juvenoids containing the cyclopentane ${ }^{2,3}$ or cyclohexane ${ }^{4}$ ring.

In this work we present the syntheses of further juvenoids with the cyclohexane system representing the cyclic analogs of the aliphatic juvenoids described earlier ${ }^{5,6}$ or synthesized by us ${ }^{7}$. Comparing the structures of both classes of juvenoids (Scheme 1), one can see that they differ in the structure of the terminal isoprenoid segment and that this segment in the cyclic structure is "rolled" in the cyclohexane or cyclohexene ring by junction of the carbon atoms $\mathrm{C}-11$ and C -14 in esters or $\mathrm{C}-7$ and $\mathrm{C}-10$ in ethers. This junction limits the flexibility of the isoprenoid chain and fixes the geometry of the $\mathrm{C}_{8}-\mathrm{C}_{9}, \mathrm{C}_{9}-\mathrm{C}_{10}$, and $\mathrm{C}_{10}-\mathrm{C}_{11}$ (in esters) or $\mathrm{C}_{4}-\mathrm{C}_{5}, \mathrm{C}_{5}-\mathrm{C}_{6}$, and $\mathrm{C}_{6}-\mathrm{C}_{7}$ bonds (in ethers) as $s$-cis, and the $\mathrm{C}_{7}{ }^{-}$ $\mathrm{C}_{8}$ (in esters) or $\mathrm{C}_{3}-\mathrm{C}_{4}$ bonds (in ethers) as $s$-trans.

## Scheme 1

Results and Discussion
Starting materials for the direct synthesis of the juvenoid alcohols 7 and $\mathbf{8}$ were obtained from dimedone (1), the reaction sequence being shown in Scheme 2.

The $\alpha, \beta$-unsaturated ketone $\mathbf{3}$ was prepared by the method of Frank and Hall ${ }^{8}$. Dimedone (1) was first converted into ethoxyketone 2 which was then reduced with $\mathrm{LiAlH}_{4}$ to give ketone 3 in $91 \%$ yield. Ketone $\mathbf{3}$ was reduced $\left(\mathrm{LiAlH}_{4}\right)$ to the allylic alcohol $\mathbf{4}$ which after Claisen rearrangement by the orthoacetate method ${ }^{9}$ (with ethyl orthoacetate) afforded the $\gamma, \delta$-unsaturated ester 5. This compound was hydrogenated over $\mathrm{Pd} / \mathrm{C}$ yielding the saturated ester 6 . Alcohols 7 and $\mathbf{8}$ were obtained by the reduction $\left(\mathrm{LiAlH}_{4}\right)$ of esters 5 and $\mathbf{6}$, respectively.

The first and the most numerous group of juvenoids, namely the esters 15-18, were obtained by the Wadsworth-Emmons reaction ${ }^{10}$ of ketones 13 or $\mathbf{1 4}$ (esters $\mathbf{1 5}$ and $\mathbf{1 7}$ from 13, or $\mathbf{1 6}$ and 18 from 14) with appropriate alkyl (diethylphosphono)acetates (s. Scheme 3).

Ketone $\mathbf{1 3}$ was obtained from alcohol 7 via tosylate 9 and bromide 11 which was used for alkylation of ethyl acetoacetate. Alkaline hydrolysis

and subsequent decarboxylation of the intermediate keto ester afforded ketone 13 in $77 \%$ yield. Ketone 14 was obtained from alcohol $\mathbf{8}$ by the following reaction sequence: alcohol 8 was oxidized with pyridinium chlorochromate ${ }^{11}$ to aldehyde 20 which was subjected to the Wittig reaction with $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{CHCOCH}_{3}$ to give the $\alpha, \beta$-unsaturated ketone 12 $(92 \%)$; the ( $E$ )-configuration of the double bond formed in 12 was confirmed by the IR $\left(970 \mathrm{~cm}^{-1}\right)$ and ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra ( $J=16 \mathrm{~Hz}$ for olefinic protons); ketone $\mathbf{1 2}$ was hydrogenated over Raney-nickel to ketone 14.
$\alpha, \beta$-Unsaturated esters $\mathbf{1 5 - 1 8}$ were obtained as isomeric $(E, Z)$ mixtures. Pure isomers were isolated by means of column chromatography. The $(Z)$-configuration was assigned to isomers for which the doublet from the methyl group at $\mathrm{C}-3$ was at higher field ( $\delta=2.17 \mathrm{ppm}$ ) in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum, and the ( $E$ )-configuration for those at lower field ( 2.42 ppm , deshielding effect of the ester group cis-oriented in relation to
the methyl group). The dienoic esters 21 and 22 [mixtures of isomers $(2 Z, 4 E)$ and $(2 E, 4 E)]$ were obtained from the reaction of aldehydes 19 or 20 with isopropyl 4-(diethylphosphono)-3-methyl-2-butenoate [mixture $(Z):(E)=48: 52$ ]. Pure isomers of these esters were isolated by

means of preparative column chromatography and the corresponding configurations were assigned based on the position of signals from the methyl group at C-3 and the olefinic proton $\mathrm{H}-4$ in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra. The signal of the methyl group for isomers $(2 Z, 4 E)$ occurred at 2.13 ppm and the multiplet of proton $\mathrm{H}-4$ at 7.84 ppm (deshielding effect of the ester group), whereas for isomers ( $2 E, 4 E$ ) the corresponding signals were at 2.52 and $6.22-6.38 \mathrm{ppm}$.

The $\gamma, \delta$-unsaturated esters $\mathbf{2 5 a} \mathbf{a}, \mathbf{b}$ and $\mathbf{2 6 a} \mathbf{a}, \mathbf{b}$ were also obtained from aldehydes 19 and 20 by the Grignard reaction with 1-propenylmagnesium
bromide [above $95 \%$ of the ( $E$ )-isomer] and subsequent Claisen rearrangement of alcohols $\mathbf{2 3}$ or $\mathbf{2 4}$ formed with methyl or ethyl orthoacetate.

Compounds 23-26 possess two chiral carbon atoms, each of them should occur as a pair of racemic diastereoisomers. Gas-chromatographic analysis (column 3 m length, $15 \%$ Carbowax 1000 on Chromosorb P, $130^{\circ} \mathrm{C}$ ) of alcohols $\mathbf{2 3}$ and 24 showed that these compounds are indeed the equimolar mixtures of diastereoisomers. This fact was also confirmed by the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra of $\mathbf{2 3}$ and 24 with the use of shift reagent $\mathrm{Eu}(T F C)_{3}$ applied for determination of enantiomeric purity. Changes of positions of signals from the gem-methyl groups were observed in these spectra. In the case of alcohol 24, whose "normal" ( 100 MHz ) ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum exhibited only one six-proton singlet derived from these groups, the spectrum with $\mathrm{Eu}(T F C)_{3}$ (dose ca. 120 mg in $5 \%$ solution of 24 in $\mathrm{CCl}_{4}$, $T M S$ as external standard) showed the presence of two pairs of singlets ( $J=15 \mathrm{~Hz}$ ) indicating that four enantiomers, forming a pair of diastereoisomeric racemic mixtures, are involved. Alcohol 23, exhibiting two singlets from the gem-methyl groups in the 100 MHz NMR spectrum, showed two groups ( $J=17 \mathrm{~Hz}$ ) four singlets each in the spectrum with the use of $\mathrm{Eu}(T M C)_{3}$.

Unfortunately, in the case of esters $25 \mathrm{a}, \mathrm{b}$ and $26 \mathrm{a}, \mathrm{b}$, neither gas chromatography nor application of $\mathrm{Eu}(T F C)_{3}$ for measurement of the ${ }^{1} \mathrm{H}$ NMR spectra $(100 \mathrm{MHz})$ afforded any data about the composition of mixtures of diastereoisomers. However, since starting compounds for the Claisen reaction, alcohols 23 and 24, are the mixtures of diastereoisomers, the products of this rearrangement are most certainly also such mixtures ${ }^{12,13}$.

The last group of juvenoids, the alkyl aryl ethers $27 \mathbf{a}, \mathbf{b}$ and $28 \mathbf{a}, \mathbf{b}$, were obtained by alkylation of potassium $p$-chloro- or $p$-ethylphenolates with tosylates $\mathbf{9}$ or $\mathbf{1 0}$.

The biological activity of the juvenoids obtained was tested on larvae of Dysdercus cingulatus and pupae of Tenebrio molitor. The results of tests showed that these compounds are moderately active on Dysdercus $c$. and inactive on Tenebrio $m$. Comparison of doses of aliphatic juvenoids and their cyclic analogs at which metamorphosis of insects is disturbed, indicates that the former compounds are about ten times more active than the latter ones.

More detailed results of biological investigations and conclusions therefrom will be the subject of a separate paper.

## Experimental

The course of all reactions and the purity of products were controlled by means of thin-layer (TLC) and gas-liquid (GLC) chromatography. TLC was carried out on silica gel $G$ (Merck). Chromatograms were developed with mixtures
of petroleum ether, ethyl ether and acetone in various ratios and detected with $20 \%$ ethanolic $\mathrm{H}_{2} \mathrm{SO}_{4}$. Preparative column chromatography was carried out on silica gel ( $100-200$ mesh, Marchery-Nagel), the eluent being a petroleum etherethyl ether-acetone mixture (various ratios). GLC was performed on a Chromatron GCHF-18.3.4 apparatus using columns with 2 and 3 m length coated with $10 \%$ XE- 60 on Chromosorb G.

The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra were recorded for $10 \% \mathrm{CCl}_{4}$ solutions on a 100 MHz Tesla BS-497 apparatus with HMDS as external standard. The IR spectra were taken for the same solutions on a Perkin-Elmer 621 spectrophotometer.

The starting material was commercial dimedone (1, 5,5-dimethyl-1,3cyclohexanedione) from POCh, m.p. $147-148^{\circ} \mathrm{C}$.

The experimental $\mathrm{C}, \mathrm{H}$ values agree with the molecular formulas given.

Alcohol $8(4.0 \mathrm{~g}, 0.026 \mathrm{~mol})$ was added in one portion to a slurry of pyridinium chlorochromate $(11.2 \mathrm{~g}, 0.052 \mathrm{~mol})$ and anhydrous sodium acetate $(0.7 \mathrm{~g}$, $0.008 \mathrm{~mol})$ in anhydrous methylene chloride ( 100 ml ) and the mixture was stirred for 2 h . Then $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was distilled off and the residue was extracted with petroleum ether. The ethereal solution was filtered through "Florisil" and evaporated. The crude product was chromatographed on a column (petroleum ether-ethyl ether $19: 1)$ and distilled in vacuo. Pure aldehyde $20(3.0 \mathrm{~g}, 76 \%)$ was obtained. Pure aldehyde 19 (yield $51 \%$ ) was obtained analogously from alcohol 7.

Alkyl aryl ethers ( $27 \mathrm{a}, \mathrm{b}$ and $28 \mathrm{a}, \mathrm{b}$ )
Tosylate 9 or $10(0.005 \mathrm{~mol})$ in $\operatorname{DMF}(5 \mathrm{ml})$ was added to the appropriate potassium phenolate (from 0.006 mol of phenol and 0.006 mol of powdered KOH ) in $D M F(20 \mathrm{ml})$. The mixture was stirred until all tosylate reacted (TLC). Then the mixture was diluted with water and the product was extracted with petroleum ether. Extracts were washed with $5 \% \mathrm{KOH}$ solution, then with water, and dried over $\mathrm{MgSO}_{4}$. The crude products were purified by means of column chromatography (petroleum ether--acetone $49: 1$ ) and distillation.
