# Reaction of Diphenyldiazomethane with $N$-Methyloxy- and $N$-Ethyloxycarbonyl- $N$-(2,2,2-trichloroethylidene)amines 

Sandrine Jacquot, ${ }^{[a]}$ Abdelhak Belaissaoui, ${ }^{[a]}$ Gérard Schmitt,* ${ }^{[a]}$ Bernard Laude, ${ }^{[a]}$ Marek M. Kubicki, ${ }^{[b]}$ and Olivier Blacque ${ }^{[b]}$

Keywords: 1,3-Dipolar cycloadditions / Diphenyldiazomethane / N-Alkyloxycarbonyl- $N$-(2,2,2-trichloroethylidene)amines / $\Delta^{3}$-1,3,4-Triazoline / Aziridines / Azomethine ylides / 2-Azadiene

Reaction of the title imines with diphenyldiazomethane gives a $\Delta^{3}$-1,3,4-triazoline, which leads, after loss of dinitrogen, to a transient azomethine ylide. Subsequent elimination of
ethyl or methyl chloroformate gives the unexpected 1,1-diphenyl-4,4-dichloro-2-aza-1,3-butadiene.

## Introduction

The known reactivity of the $\mathrm{C}=\mathrm{N}$ double bond in various azomethines towards diazoalkanes leads to the regioselective formation of $\Delta^{2}$-1,2,3-triazolines. ${ }^{[1-4]}$ However, some examples of the formation of $\Delta^{3}$-1,3,4-triazolines have also been reported. ${ }^{[1][4]}$ It has often been observed that thermolysis of the triazolines gives the corresponding aziridines or other products resulting from the loss of dinitrogen.
We present here the reactions of diphenyldiazomethane $\mathbf{2}$ with $N$-ethyloxy- and $N$-methyloxycarbonyl- $N$-(2,2,2-trichloroethylidene)amines $\mathbf{1 a}$ and $\mathbf{1 b}$. The 1,3-dipolarophilic reactivity of the electron-deficient imine $\mathbf{1 a}$ has recently been assessed using 1,3-dipoles such as nitrones, ${ }^{[5]}$ nitrilimines and nitriloxides, ${ }^{[6]}$ as well as ethyl diazoacetate. ${ }^{[7]}$ In this last case, the reaction involves nucleophilic addition of the ethyl diazoacetate with formation of a new 1,3-dipole. ${ }^{[7]}$ This addition should not occur with diphenyldiazomethane since this 1,3-dipole has no mobile proton.

## Results and Discussion

## Reactions

After stirring a toluene solution of the imine $\mathbf{1 a}$ or $\mathbf{1 b}$ with diphenyldiazomethane 2 for 24 h at $65^{\circ} \mathrm{C}$, a major product $3(70 \%)$ was formed, together with a by-product 4 (7\%). Elemental analysis, IR, and NMR data of $\mathbf{3}$ were not consistent with the structure of the expected triazoline. The structure of this product was later unambiguously established by an X-ray diffraction study (Figure 1). Elemental analysis and spectroscopic data showed $\mathbf{4}$ to be an aziridine

[^0]commonly found as a secondary product of the expected triazoline. ${ }^{[1]}$

Scheme 1. Reaction of 1a,b with 2 at $65^{\circ} \mathrm{C}$

Figure 1. ORTEP plot ( $50 \%$ probability level) of the molecular structure of 3

Formally, compound $\mathbf{3}$ is a secondary product formed by loss of dinitrogen and alkyl chloroformate from a triazoline 1,3 -cycloadduct of $\mathbf{1}$ with $\mathbf{2}$. Indeed, a quantitative gas-
chromatographic analysis of the reaction mixture of $\mathbf{1 a}$ with 2 led to the detection of $>80 \%$ of the estimated stoichiometric amount of ethyl chloroformate.
The 2-azadiene 3 may also be formed from the aziridine 4 following loss of alkyl chloroformate. According to literature data, ${ }^{[1]}$ heating to a temperature $>100^{\circ} \mathrm{C}$ allows cleavage of the $\mathrm{C}-\mathrm{C}$ bond of an aziridine ring, leading to the corresponding azomethine ylide. Indeed, while $\mathbf{4 a}$ is thermally stable at $65^{\circ} \mathrm{C}$, refluxing a toluene solution of this compound results in quantitative conversion to the 2 -azadiene 3 and ethyl chloroformate, this process certainly proceeding via the azomethine ylide 5a (Scheme 2).

Scheme 2. Evolution of $\mathbf{4 c}$ at $110^{\circ} \mathrm{C}$
In order to identify some of the transient species leading to the 2 -azadiene 3 , which should allow elucidation of the mechanism of the reaction, we carried out a study at room temperature. After 30 h at this temperature, a mixture of the imine $\mathbf{1 a}$ or $\mathbf{1 b}$ and diphenyldiazomethane $\mathbf{2}$ in toluene solution gave only one isolable product (yield: $70 \%$ ), elemental analysis and spectrometric data of which showed it to be one of the two regioisomeric triazolines $\mathbf{6}$ or $\mathbf{6}^{\prime}$ formed by 1,3-dipolar cycloaddition (Scheme 3).

Scheme 3. Reaction of $\mathbf{1 a}, \mathbf{b}$ with 2 at $20^{\circ} \mathrm{C}$
With the aim of determining the direction of addition of this cycloadduct, we tried to undertake an X-ray crystal structure analysis. However, all attempts to obtain suitable single crystals were unsuccessful. Thus, the structure of the $\Delta^{3}$-1,3,4-triazoline 6 was established on the basis of its ${ }^{1} \mathrm{H}$ NMR data: The chemical shift of the $5-\mathrm{H}$ proton $\left(\mathrm{Cl}_{3} \mathrm{CCH}\right)$
at $\delta>7.50$ is in good agreement with structure $\mathbf{6}$, where the CH group resides between two deshielding nitrogen atoms. In the case of structure $\mathbf{6}^{\prime}$, this signal would be expected to appear below $\delta=6.00 .{ }^{[8]}$ The signals of the alkyl ester groups are broadened (see Figure 2 for the case of 6a), probably due to restricted rotation because of the steric hindrance imposed by the 2,2 -diphenyl groups and the $5-\mathrm{CCl}_{3}$ moiety. Such hindrance should not be present in the triazolinic structure $\mathbf{6}^{\prime}$. Moreover, ${ }^{1} \mathrm{H}-\mathrm{NMR}$ examination of the mother liquor of $\mathbf{6}$ did not reveal the expected signal of the $5-\mathrm{H}$ proton $(\delta \approx 5.50-6.00)$ of the regioisomer $\mathbf{6}^{\prime}$.

We attempted to rationalize the direction of the addition by carrying out some semi-empirical MO calculations (PM3 level, optimized geometries) on the starting reactants $\mathbf{1 b}$ and $\mathbf{2}$. The results of these calculations show that the cycloaddition occurs by interaction between the LUMO of 1b and the HOMO of $\mathbf{2}$. However, it is not possible to justify the observed direction of addition since the orbital coefficients of the C and N atoms of the LUMO of $\mathbf{1 b}$ have equal weightings.

## Study of the Evolution of Cycloadduct 6a

We observed that heating a solution of cycloadduct 6a in toluene at $65^{\circ} \mathrm{C}$ furnished 2-aza-1,3-butadiene 3 in high yield ( $>90 \%$ ). Thus, we tried to follow this evolution in an NMR tube in $\mathrm{CDCl}_{3}$ at $50^{\circ} \mathrm{C}$ over a period of 10 h (Figure 2 ).

Figure 2. Evolution of the triazoline 6a at 323 K
This study revealed that 6a is not transformed directly to the final 2-azadiene 3. In fact, a second intermediate $\mathbf{5}$ is involved. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of this transient species 5 features well-resolved signals for the ethyl group of the ester function. The absence of steric hindrance is probably due to a ring-opening of $\mathbf{6 a}$, leading to two possible transient species 5a or $\mathbf{5}^{\prime} \mathbf{a}$. The azomethine ylide structure 5a would be formed from $\mathbf{6 a}$ by 1,3-dipolar cycloreversion and loss of dinitrogen, while the $N$-(2,2-dichlorovinyl)iminium

Scheme 4. Evolution of $\mathbf{6 a}$ at 323 K
salt $5^{\prime}$ a would arise by loss of one chloride ion ${ }^{[9]}$ (Scheme 4).

We favour the azomethine ylide structure 5a for the intermediate because in some of the recorded ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra the signals of aziridine $\mathbf{4 a}$ appeared after the formation of the transient species $\mathbf{5}$. Compound $\mathbf{4 a}$ can only be derived from ring-closure of the azomethine ylide 5a (Scheme 5). It is obtained at $50-65^{\circ} \mathrm{C}$.

Scheme 5. Ring closure of 5
The structure 5a may be further supported by a transient orange coloration of the solution in the NMR tube. However, all attempts to trap this 1,3-dipole 5a by cycloaddition with $N$-phenyl- or $N$-methylmaleimide or with DMAD proved unsuccessful. This may be attributable to the steric hindrance of the three atoms of the dipole 5a rendering this species unreactive.

## Conclusion

This study has established the successive steps of the mechanism of the title reaction. The primary cycloadduct 6a leads, after loss of dinitrogen, to a transient azomethine ylide 5a. Subsequent elimination of alkyl chloroformate gives the 1,1-diphenyl-4,4-dichloro-2-aza-1,3-butadiene 3 . To the best of our knowledge, this is the first example of the formation of a 2-azabutadiene as a secondary product of an azomethine ylide. Work is currently in progress aimed at extending this reaction to other disubstituted diazoalkanes and other conveniently substituted imines

## Experimental Section

General: IR spectra ( KBr ) were recorded on a Bio-Rad FTS-7 spectrometer. $-{ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR spectra were obtained on a Bruker Spectrospin AC 200 spectrometer operating at 200 MHz for ${ }^{1} \mathrm{H}$ and
at 50.3 MHz for ${ }^{13} \mathrm{C}$. Chemical shifts were measured relative to TMS in $\mathrm{CDCl}_{3}$ or $\left[\mathrm{D}_{8}\right]$ THF as solvents. - Analytical data were obtained at the Elemental Analysis Center, Dijon. - Melting points were determined on an Electrothermal 9200 apparatus and are uncorrected. $-N$-Ethyloxy- and $N$-methyloxycarbonyl- $N$ -(2,2,2-trichloroethylidene)amines ${ }^{[10][11]}$ and diphenyldiazomethane ${ }^{[12]}$ were synthesized according to literature methods.

Reactions at $65^{\circ}$ C. - General Procedure: A solution of diphenyldiazomethane ( 32 mmol ) and $N$-ethyloxy- or $N$-methyloxycarbonyl- N -(2,2,2-trichloroethylidene) amine ( 32 mmol ) in toluene $(80 \mathrm{~mL}$ ) was heated at $65^{\circ} \mathrm{C}$ for 24 h . The solvent was then evaporated and the residue was recrystallized from ethanol.
(a) Synthesis of 4,4-Dichloro-1,1-diphenyl-2-azabuta-1,3-diene (3): Yield: $70 \%$, pale-yellow needles, m.p. $122^{\circ} \mathrm{C} .-{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right)$ : $\delta=7.05(\mathrm{~s}, 1 \mathrm{H}$, ethylenic CH$), 7.15-7.80(\mathrm{~m}, 10 \mathrm{H}$, arom. H). ${ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=123.4\left(\mathrm{~s},=\mathrm{CCl}_{2}\right), 128.2-131.0(5$ signals for 10 arom. CH ), 135.2 (d, ethylenic CH ), 135.4 (s, arom. C), 138.5 (s, arom. C), $168.3(\mathrm{~s}, \mathrm{C}=\mathrm{N}) .-\mathrm{C}_{15} \mathrm{H}_{11} \mathrm{Cl}_{2} \mathrm{~N}$ (276.18): calcd. C 65.24, H 4.01, N 5.07, Cl 25.68; found C 65.19, H 3.99, N 5.10, Cl 25.72.

X-ray Crystal Structure of 3: The structure was solved by direct methods using SHELXS-97. Hydrogen atoms were placed in calculated positions. Refinement was carried out by a full-matrix leastsquares method based on $F^{2}$ values with 163 variables. Crystallographic data are collected in Table 1. Selected bond lengths [A] and angles [ ${ }^{\circ}$ ] for 3: $\mathrm{C} 1-\mathrm{C} 21.319(3), \mathrm{N}-\mathrm{C} 21.392(3), \mathrm{N}-\mathrm{C} 31.293(2)$; $\mathrm{C} 1-\mathrm{C} 2-\mathrm{N} 121.2(2), \mathrm{C} 2-\mathrm{N}-\mathrm{C} 3119.7(2), \mathrm{N}-\mathrm{C} 3-\mathrm{C} 4117.5(2)$, $\mathrm{N}-\mathrm{C} 3-\mathrm{C} 10 \quad 125.2(2), \quad \mathrm{C} 4-\mathrm{C} 3-\mathrm{C} 10 \quad 117.3(2), \quad \mathrm{Cl} 1-\mathrm{C} 1-\mathrm{Cl} 2$ 114.6(1). For further information see ref. ${ }^{\text {[13] }}$
(b) Synthesis of Aziridines 4a and 4b: The mother liquor from the above crystallization was concentrated and the newly obtained residue was crystallized from ethanol. Ethyl- and methyl 2,2-diphenyl-3-(trichloromethyl)aziridine-1-carboxylates $\mathbf{4 a}$ and $\mathbf{4 b}$ were obtained as pale-yellow needles (each $2.56 \mathrm{mmol}, 7 \%$ ).
Ethyl 2,2-Diphenyl-3-(trichloromethyl)aziridine-1-carboxylate (4a): Yield: $7 \%$, m.p. $101{ }^{\circ} \mathrm{C}$. - IR (KBr): $\tilde{v}=1720 \mathrm{~cm}^{-1}(\mathrm{C}=\mathrm{O}) .-{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=1.06\left(\mathrm{t},{ }^{3} J=7.1 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{CO}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 4.00$ (AB part of $\mathrm{ABX}_{3},{ }^{3} J=7.1 \mathrm{~Hz},{ }^{2} J=10.7 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{CO}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ ), $\left.4.52(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CHCCl})_{3}\right), 7.20-7.65\left(\mathrm{~m}, 10 \mathrm{H}\right.$, arom. H). $-{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=13.85\left(\mathrm{q}, J=127 \mathrm{~Hz}, \mathrm{CO}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 57.9(\mathrm{~d}, J=$ $\left.174 \mathrm{~Hz}, \mathrm{CHCCl}_{3}\right), 60.5(\mathrm{~s}, \mathrm{Cq}), 63.0\left(\mathrm{t}, J=148 \mathrm{~Hz}, \mathrm{CO}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\right)$, $96.2\left(\mathrm{~s}, \mathrm{CCl}_{3}\right), 127.7-129.0$ (6 signals for 10 arom. CH ), 135.8-136.8 (2 signals for 2 arom.
