of such a chelate, that is, the direct correlation of the crystalline and solution circular dichroism spectra with crystallographic results, rather than the more empirical assignments based on the use of model ligands, more kinetically inert metal-ion complexes, or closely related compounds relied on much in the past. Two additional conclusions can be drawn from our observations. In the case of ferric chelates of biological interest, it is necessary to compare the absolute configuration of the molecule in the solid state with that in solution. This communication represents such an example, and, in absence of an anomalous dispersion experiment, single-crystal and solution circular dichroism spectroscopy offers a seemingly satisfactory method. Our results can also be used to rationalize the apparent inactivity of the Penicillium esterase toward the aluminum chelate of $N, N^{\prime}, N^{\prime \prime}$-triacetylfusarinine ${ }^{14}$ by assuming stereochemical specificity of the esterase and a slow rate of equilibrium for the chelate. Finally, it is noteworthy that our findings do not allow the prediction of which diasteroisomer ( $\Lambda$-cis or $\Delta$-cis) of ferric $N, N^{\prime}, N^{\prime \prime}$-triacetylfusarinine is actively transported across the microbial cell membrane. Experimentally, this question will be approached by performing the transport experiments with chromatographically resolved diastereoisomers of the chelate of a kinetically inert metal ion, such
as $\mathrm{Cr}(\mathrm{III})$ or $\mathrm{Co}(\mathrm{III})$. This method was successfully used in probing the transport of ferrichrome in Ustilago sphaerogena, using resolved $\Lambda$-cis and $\Delta$-cis chromic deferriferrichrome. ${ }^{42}$

Acknowledgments. We wish to express our gratitude to Dr. Neil Purdie, Department of Chemistry, Oklahoma State University, Stillwater, for the use of the spectropolarimeter, John M. Bowen for his expert technical assistance in obtaining the CD data, and Mr. Fred E. Dillon for his technical help in obtaining the mass-spectral data. One of the authors (D.v.d.H.) expresses his gratitude to Dr. T. Emery, Utah State University, for the help and hospitality he received while working in his laboratory. This research was sponsored by the National Institute of General Medical Sciences (GM 21822).

# Synthesis and Crystal and Molecular Structure of $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{2} \mathrm{~N}^{+}\right]\left[\mathrm{S}_{4} \mathrm{~N}^{-}\right]$and the Electronic Structure of the Planar Acyclic Anion, $\mathrm{S}_{4} \mathrm{~N}^{-1}$ 

T. Chivers,* W. G. Laidlaw, R. T. Oakley, and M. Trsic<br>Contribution from the Department of Chemistry, University of Calgary, Calgary T2N 1N4, Alberta, Canada. Received February 5, 1980

#### Abstract

The thermal decomposition of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}_{5}{ }^{-}\left[\mathrm{PPN}^{+}=\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{2} \mathrm{~N}^{+}\right]$in acetonitrile at $78{ }^{\circ} \mathrm{C}$ leads, sequentially, to the corresponding salts of the $\mathrm{S}_{3} \mathrm{~N}_{3}{ }^{-}$and $\mathrm{S}_{4} \mathrm{~N}^{-}$anions. The crystal and molecular structure of the dark blue salt, PPN ${ }^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$, has been determined by X-ray crystallography. The compound crystallized in the space group $P \overline{1}$, triclinic, $a=11.220$ (2) $\AA, b=16.860(3) \AA, c=9.862$ (2) $\AA, \alpha=99.17(1)^{\circ}, \beta=98.04(1)^{\circ}, \gamma=71.56(1)^{\circ}, V=1739.2 \AA^{3}$, and $Z=2$. The refined structure ( $R_{1}=0.064$ ) shows that the $S_{4} \mathrm{~N}^{-}$anion is an essentially planar, cis, trans chain with nitrogen as the central atom. The terminal $S-S$ bond distances are remarkably short (1.879 (3) and 1.943 (2) $\AA$ ), while the $S-N$ bond lengths show a pronounced inequality ( $1.667(5)$ and $1.521(5) \AA)$. The bond angles at the internal sulfur atoms are ca. $110.5(2)^{\circ}$ and the angle at nitrogen is $120.8(3)^{\circ}$. Infrared and Raman spectra of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$and $\mathrm{PPN}^{+} \mathrm{S}_{4} * \mathrm{~N}^{-}$(where $* \mathrm{~N}=30 \%{ }^{15} \mathrm{~N}$ ) demonstrate that the vibrational frequencies at ca. 592 and $565 \mathrm{~cm}^{-1}$ can be assigned to the stretching modes of the unequal $\mathrm{S}-\mathrm{S}$ bonds. Ab initio Hartree-Fock-Slater SCF calculations have been carried out for $\mathrm{S}_{4} \mathrm{~N}^{-}$and show that the calculated statistical energy of the experimental conformation is not substantially lower than that of the symmetrical cis, trans or trans, trans conformations of the anion. The ground-state electronic structure of $\mathrm{S}_{4} \mathrm{~N}^{-}$is an $8 \pi$-electron system. The strong absorption in the visible spectrum at 582 nm appears to be the result of a $\pi^{*}(\mathrm{HOMO}) \rightarrow \pi^{*}(\mathrm{LUMO})$ transition. The $\mathrm{S}-\mathrm{N}$ linkages can be described approximately as net $2 / 3 \sigma$ plus $1 / 2 \pi$ bonds, while the $S$-S bonds are approximately $5 / 4 \sigma$ plus $1 / 4 \pi$. The terminal sulfur atoms each carry two lone pairs of electrons and bear large negative charges, -0.42 and -0.44 , as does the nitrogen, -0.35 ; the internal sulfur atoms have one lone pair of electrons and have small positive charges, +0.01 and +0.20 . The experimental conformation may be the result of an electrostatic interaction between terminal and internal sulfur atoms.

## Introduction

The formation of a blue color on deprotonation of cyclic sulfur imides, e.g., $\mathrm{S}_{7}$ NH, in basic media is used as a spot test in the chromatographic separation of these imides for $\mathrm{cyclo}-\mathrm{S}_{8} .{ }^{2}$ The same deep blue color is also dramatically apparent during the preparation of sulfur imides from (a) sulfur monochloride and ammonia in $\mathrm{DMF}^{2}$ or (b) sodium azide and cyclo- $\mathrm{S}_{8}$ in HMPA. ${ }^{3}$ A number of attempts to identify the species responsible for the

[^0]blue color have been made. The suggestion that it is a neutral sulfur radical $S_{x}(x=2-4)^{4}$ was shown to be incorrect by Chapman and Massey, who demonstrated that it was negatively charged and diamagnetic; they proposed it to be the $\mathrm{S}_{7} \mathrm{~N}^{-}$anion. ${ }^{5}$ Subsequent work by Olsen and Olsen established the presence of cyclo- $\mathrm{S}_{7} \mathrm{~N}^{-}$in solutions resulting from the deprotonation of $\mathrm{S}_{7} \mathrm{NH}$ with various bases. ${ }^{6}$ On the basis of detailed studies of the alkylation of such solutions, these workers suggested that cyclo$\mathrm{S}_{7} \mathrm{~N}^{-}$was in equilibrium with other anions, including an "open-

[^1]chain" anion. ${ }^{6}$ In 1973, Mendelsohn and Jolly reported the preparation of cyclo- $\mathrm{S}_{7} \mathrm{~N}^{-}$from $\mathrm{S}_{7} \mathrm{NH}$ and powdered KOH in THF. ${ }^{7}$ These workers showed that the cyclic anion was yellow and stable at $-78^{\circ} \mathrm{C}$ but that, on warming above $-40^{\circ} \mathrm{C}$, it spontaneously isomerized, probably to an open-chain form of $\mathrm{S}_{7} \mathrm{~N}^{-}$; they were unable to decide if the latter species was responsible for the predominantly blue color of $\mathrm{K}^{+} \mathrm{S}_{7} \mathrm{~N}^{-}$solutions at $0^{\circ} \mathrm{C}$. ${ }^{7}$ In the same year, Chivers and Drummond described the isolation and characterization of a dark blue salt, $n-\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$, following the deprotonation of cyclo-S, NH with tetra- $n$-butylammonium hydroxide in diethyl either. ${ }^{8}$ This product was obtained, mixed with cyclo- $\mathrm{S}_{8}$, by the disproportionation of yellow $n-\mathrm{Bu}_{4} \mathrm{~N}^{+}-c y-$ clo- $\mathrm{S}_{7} \mathrm{~N}^{-}$at $23^{\circ} \mathrm{C}$. On the basis of a comparison of the vibrational spectra with those of the isoelectronic $\mathrm{CS}_{4}{ }^{2-}$ ion, ${ }^{9}$ a branched-chain structure was proposed for $\mathrm{S}_{4} \mathrm{~N}^{-86}$ Such a structure has now been confirmed for $\mathrm{CS}_{4}{ }^{2-}$ by X-ray crystallography. ${ }^{10}$ However, numerous attempts in our laboratory to obtain crystals of $\mathrm{S}_{4} \mathrm{~N}^{-}$, with different cations, have been unsuccessful until the present study.

As part of our investigations of the thermolysis of $\mathrm{S}-\mathrm{N}$ compounds we have discovered that the $\mathrm{S}_{4} \mathrm{~N}_{5}^{-}$ion decomposes smoothly in boiling acetonitrile to give the $\mathrm{S}_{4} \mathrm{~N}^{-}$anion and, as a salt with PPN $^{+}$, crystals suitable for X-ray crystallography can be obtained. ${ }^{1}$ In this paper we report the full details of the synthesis and crystal and molecular structure of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$. In addition we have carried out ab initio Hartree-Fock-Slater (HFS) SCF calculations of $\mathrm{S}_{4} \mathrm{~N}^{-}$in order to (a) obtain an MO description of the ground-state electronic structure, (b) determine the energy of the experimental conformation relative to other conformations, (c) ascertain the importance, if any, of long-range S -S interactions in the anion, and (d) assign the intense absorption in the visible spectrum to the appropriate electronic transition.

## Experimental Section

Materials. Tetrasulfur tetranitride was prepared according to the literature method. ${ }^{11}$ Piperidinium tetrasulfur pentanitride, $\left(\mathrm{CH}_{2}\right)_{5} \mathrm{NH}_{2}{ }^{+} \mathrm{S}_{4} \mathrm{~N}_{5}^{-}$, was prepared by the reaction of anhydrous piperidine with $\mathrm{S}_{4} \mathrm{~N}_{4}$ in absolute ethanol. ${ }^{12}$ Bis(triphenylphosphine) iminium tetrasulfur pentanitride, $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}_{5}^{-}$, was then prepared by cation exchange of $\left(\mathrm{CH}_{2}\right)_{5} \mathrm{NH}_{2}{ }^{+} \mathrm{S}_{4} \mathrm{~N}_{5}^{-}$with $\mathrm{PPN}^{+} \mathrm{Cl}^{-}$(Aldrich) in water (yield ca. 100\%). The crude, yellow precipitate was recrystallized from hot acetonitrile to give air-stable, yellow needles of $\operatorname{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}_{5}$, which showed infrared bands characteristic of the $\mathrm{S}_{4} \mathrm{~N}_{5}{ }^{-}$anion at $955 \mathrm{~s}, 916 \mathrm{~s}, 757 \mathrm{~m}, 747 \mathrm{~m}$, $666 \mathrm{w}, 647 \mathrm{w}, 598 \mathrm{~m}, 428 \mathrm{~m}$, and $300 \mathrm{vw} \mathrm{cm}^{-1} .12,13$ The UV-visible spectrum (in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) had a band at $293 \mathrm{~nm}, \epsilon \sim 5.9 \times 10^{3} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}$, with a shoulder at $345 \mathrm{~nm}, \epsilon \sim 2.5 \times 10^{3} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}$. Bis(triphenylphosphine) iminium trisulfur trinitride, $\mathrm{PPN}^{+} \mathrm{S}_{3} \mathrm{~N}_{3}^{-}$, was prepared by the reaction of $\mathrm{PPN}^{+} \mathrm{N}_{3}{ }^{-14}$ with $\mathrm{S}_{4} \mathrm{~N}_{4}$ (1:1 mole ratio) in absolute ethanol, using the procedure already described for the preparation of $\mathrm{S}_{3} \mathrm{~N}_{3}{ }^{-}$salts. ${ }^{15}$ The crude yellow product was filtered off under nitrogen, extracted with pentane to remove cyclo- $\mathrm{S}_{8}$, and recrystallized from anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /methanol to give lime-green blocks ( $66 \%$ yield), which decompose slowly on prolonged exposure to air. $\mathrm{PPN}^{+} \mathrm{S}_{3} \mathrm{~N}_{3}$ - showed infrared bands characteristic of the $\mathrm{S}_{3} \mathrm{~N}_{3}{ }^{-}$ion at 925 vw and $642 \mathrm{~s} \mathrm{~cm}^{-1}$. ${ }^{\text {15 }}$ The UV-visible spectrum also exhibited a characteristic band at $365 \mathrm{~nm}, \epsilon$ $\sim 3.9 \times 10^{3} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1} .15$

Piperidine was stored over molecular sieves and distilled before use. Acetonitrile (reagent grade) was dried by distillation from $\mathrm{P}_{2} \mathrm{O}_{5}$ followed by distillation from calcium hydride. Ethanol and methanol (reagent grade) were dried by distillation from magnesium. All distillations of solvents and all reactions were carried out under an atmosphere of nitrogen ( $99.99 \%$ purity) passed through Ridox and silica gel.

Instrumentation. Routine infrared spectra (CsI windows) were recorded as Nujol mulls on a Perkin-Elmer 467 grating spectrophotometer.

UV-visible spectra were obtained by using a Cary 14 spectrophotometer. The infrared spectra of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$and $\mathrm{PPN}^{+} \mathrm{S}_{4} * \mathrm{~N}^{-}$were obtained for Nujol mulls ( CsI ) and solutions in $\mathrm{CH}_{3} \mathrm{CN}(\mathrm{KBr})$, using a Perkin-Elmer Model 850 ratio-recording spectrophotometer with attached computer for data handling. The Raman spectra were recorded on a Jarreli-Ash Model 25-100 double monochromator calibrated with carbon tetrachloride. A Coherent Radiation CR3 argon-ion laser was used to produce exciting lines at $457.9,488.0$, and 514.5 nm . Samples were mounted in a $6-\mathrm{cm}$ diameter ring which was rotated at about 1000 rpm to prevent thermal decomposition.

Thermolysis of $\mathbf{P P N}^{+} \mathbf{S}_{4} \mathbf{N}_{5}{ }^{-}$. A. A slurry of $\mathrm{PNP}^{+} \mathbf{S}_{4} \mathbf{N}_{5}^{-}(1.008 \mathrm{~g}, 1.37$ mmol ) in degassed acetonitrile ( 30 mL ) was heated to reflux, producing a yellow solution which slowly turned orange after a few minutes. Over the next 6 h the solution went through a series of color changes, passing from orange to red to deep red-green, and finally to deep blue. Heating was continued for another 16 h and then the mixture was cooled to $0^{\circ} \mathrm{C}$, whereupon a few crystals $(<0.02 \mathrm{~g})$ of $\mathrm{cyclo}-\mathrm{S}_{8}$ appeared, which were filtered off under nitrogen. The filtrate was evaporated in vacuo to approximately 15 mL and then cooled to $-10^{\circ} \mathrm{C}$ overnight. The following day the solution was filtered to leave lustrous, deep blue crystals of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}(0.467 \mathrm{~g}, 0.686 \mathrm{mmol}, 50 \%)$, which were washed with a little cold toluene and sucked dry. Crystals of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$(mp 155-158 ${ }^{\circ} \mathrm{C}$ with decrepitation) have a copper-like metallic sheen and are stable for several hours in air. In solution, the $\mathrm{S}_{4} \mathrm{~N}^{-}$species is very sensitive to traces of oxygen and moisture, decomposing to as yet uncharacterized oxyanions of sulfur. The UV-visible spectrum of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$exhibits a characteristically intense band at $582 \mathrm{~nm},{ }^{36} \in \sim 1.6 \times 10^{4} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}$. The details of the vibrational spectra of the $\mathrm{S}_{4} \mathrm{~N}^{-}$ion are given in the Results and Discussion section.
B. In a second experiment a slurry of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}_{5}{ }^{-}(1.007 \mathrm{~g}, 1.37$ mmol ) in degassed acetonitrile ( 30 mL ) was heated to reflux, and the color of the reaction mixture was monitored by visible spectroscopy. As soon as the blue ( $\lambda_{\max } 582 \mathrm{~nm}$ ) color of the $\mathrm{S}_{4} \mathrm{~N}^{-}$ion was observed, heating was discontinued and the solution cooled to room temperature. The volume of the solution was reduced to ca. 15 mL in vacuo, and the mixture was cooled to $0^{\circ} \mathrm{C}$ for a period of 3 h . The solution was then filtered to reveal a crystalline mixture ( 0.240 g ) containing cyclo- $\mathrm{S}_{8}$, $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}_{5}^{-}$(canary-yellow needles), and $\mathrm{PPN}^{+} \mathrm{S}_{3} \mathrm{~N}_{3}{ }^{-}$(lime-green needles). The latter two components were separated manually and identified by their infrared and UV-visible spectra.

Thermolysis of PPN ${ }^{+} \mathrm{S}_{3} \mathbf{N}_{3}{ }^{-}$. A solution of PPN ${ }^{+} \mathrm{S}_{3} \mathrm{~N}_{3}{ }^{-}(0.980 \mathrm{~g}, 1.47$ mmol ) in degassed acetonitrile ( 60 mL ) was heated to reflux, whereupon the color of the solution rapidly changed from yellow-green to deep blue. After 7 h at reflux the solution was cooled to room temperature and concentrated in vacuo to ca. 15 mL . The solution was then warmed to redissolve some $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$that had crystallized out, and the mixture was then cooled to $-10^{\circ} \mathrm{C}$ overnight. The solution was filtered and the deep blue crystals of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$were washed with a little cold toluene and sucked dry ( $0.259 \mathrm{~g}, 0.380 \mathrm{mmol}, 35 \%$ based on sulfur). A few flakes of cyclo- $\mathrm{S}_{8}$ were also present, and these were removed manually from the $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$.

Preparation of $\mathrm{PPN}^{+} \mathbf{S}_{4} * \mathbf{N}^{-}$. Isotopically enriched $\mathrm{PPN}^{+} \mathbf{S}_{4} * \mathbf{N}^{-}$(where $* \mathrm{~N}=30 \%{ }^{15} \mathrm{~N}$ ) was prepared by the thermolysis of $\mathrm{PPN}^{+} \mathrm{S}_{4} * \mathrm{~N}_{5}^{-16}$ in acetonitrile, using the procedure described above for $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$

X-ray Structural Determination of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathbf{N}^{-}$. Crystals of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathbf{N}^{-}$ suitable for X-ray work were obtained from acetonitrile. A crystal with approximate dimensions of $0.2 \times 0.2 \times 0.3 \mathrm{~mm}$ was mounted in a capillary and used for data collection.

Crystal Data (at $23 \pm 1^{\circ} \mathrm{C}$ ): $\mathrm{C}_{36} \mathrm{H}_{30} \mathrm{~N}_{2} \mathrm{P}_{2} \mathrm{~S}_{4}, M=680.86, F(000)=$ 708 , triclinic, space group $P \overline{1}$. Based on 25 reflections, the following unit cell parameters were obtained: $a=11.220$ (2) $\AA, b=16.860$ (3) $\AA, c$ $=8.862(2) \AA, \alpha=99.17(1)^{\circ}, \beta=98.04(1)^{\circ}, \gamma=71.56^{\circ}, V($ for $Z$ $=2)=1739.2 \AA^{3}, d_{\mathrm{c}}=1.300 \mathrm{~g} \mathrm{~cm}^{-3}$, and $\mu=3.9 \mathrm{~cm}^{-1}$.

Data Collection and Reduction. Intensity data were collected by using an Enraf-Nonius CAD4 automated diffractometer under the control of a PDP $11 / 45$ computer, using graphite monochromated $\mathrm{Mo} \mathrm{K} \alpha$ radiation ( $\lambda=0.71073 \AA$ ) and a $\theta-2 \theta$ scan rate varying from 4 to $40^{\circ} / \mathrm{min}$ depending on the intensity of the reflection. A counter aperture width of 2.0 mm , a crystal-to-detector distance of 21 cm , and an incident beam collimator distance of 0.7 mm were used. The scan range was $2 \theta$ (Mo $\mathrm{K} \alpha_{1}$ ) $-0.6^{\circ}$ to $2 \theta$ (Mo $\mathrm{K} \alpha_{2}$ ) $+0.6^{\circ}$ and the data range was $0^{\circ}<2 \theta$ (Mo $\mathrm{K} \alpha)<48^{\circ}$. Moving-crystal moving-counter background counts were taken at each end of the scan range. The ratio of the scan time to background counting time was 2.0 . Of the 5616 reflections collected, only the 5454 unique reflections were retained as observed and corrected for Lorentz and polarization effects. Three check reflections were measured periodically, but no changes were observed. Intensities and standard deviations were calculated by using the following formulas:

[^2]\[

$$
\begin{gathered}
I=S(C-R B) \\
\sigma(I)=\left[S^{2}\left(C+R^{2} B\right)+(p I)^{2}\right]^{1 / 2}
\end{gathered}
$$
\]

where $S$ is the scan rate, $C$ is the total background peak count, $R$ is the ratio of the scan time to background counting time, $B$ is the total background counting time, and $p$ is a factor (here set to 0.05 ) introduced to downweight intense reflections. Corrections for changes in intensity of the standard reflections, extinction, or absorption were not necessary.

Solution and Refinement of the Structure. The structure was solved by direct methods. Using 434 reflections ( $E_{\min }=1.70$ ) and 2000 phase relationships, a total of 16 phase sets were produced. From an $E$ map prepared from the phase set showing the second best probability statistics (absolute figure of merit $=1.02$, residual $=0.31$ ) a total of 39 atoms was located. These were included in a least-squares refinement, resulting in agreement factors (defined below) of $R=0.23$ and $R=0.31$. The remaining nonhydrogen atoms were located in succeeding difference Fourier syntheses. In the refinement procedure the function minimized was $\Sigma w\left(\left|F_{0}\right|-\left|F_{\mathrm{c}}\right|\right)^{2}$, where $w$ is defined as $4 F_{0}^{2} / \sigma^{2}\left(F_{\mathrm{o}}{ }^{2}\right)$. Scattering factors were taken from ref 17 . Anomalous dispersion effects were included in $F_{c}$; the values of $\Delta f^{\prime}$ and $\Delta f^{\prime \prime}$ are from ref 18. In the final cycles of refinement the 30 phenyl-ring hydrogen atoms were included in calculated positions with $\mathrm{C}-\mathrm{H}=0.95 \AA$ and $\beta_{\text {iso }}$ 's fixed at $7.0 \AA^{2}$. In the full-matrix least-squares refinement ( 44 atoms, 397 variable parameters), only the 2987 reflections having $F_{0}{ }^{2}>3 \sigma\left(F_{0}{ }^{2}\right)$ were included, resulting in a final $R=0.064$ and $R=0.083$, where

$$
\begin{gathered}
R_{1}=\Sigma| | F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{\mathrm{o}}\right| \\
R_{2}=\left[\Sigma w\left(\left|F_{\mathrm{o}}\right|-\left|F_{\mathrm{c}}\right|\right)^{2} / \Sigma w F_{\mathrm{o}}^{2}\right]^{1 / 2}
\end{gathered}
$$

The esd of an observation of unit weight was 2.26 ; the maximum parameter shift was $0.07 \sigma$. Plots of $\Sigma w\left(\left|F_{\mathrm{o}}\right|-\left|F_{\mathrm{c}}\right|\right)^{2}$ vs. $\left|F_{\mathrm{o}}\right|, \lambda^{-1} \sin \theta$, and various classes of indices showed no significant trends.

A final difference Fourier map revealed three peaks of $0.4,0.2$, and $0.2 \mathrm{e} \AA^{-3}$, which were within ca. $1.2 \AA$ of $S(3)$ and $S(4)$ (hydrogen atoms had appeared on previous maps at 0.3 e $\AA^{-3}$ ). Since the thermal parameters of the sulfurs and $N(1)$ were somewhat large and anisotropic, we ascribe these peaks to anisotropy of the sulfur atoms or a very small amount of disorder.

Theoretical Method. The single determinant closed shell description of $\mathrm{S}_{4} \mathrm{~N}^{-}$has been obtained by using the HFS procedure. The frozen core approximation described by Baerends and co-workers ${ }^{19}$ was employed for the $1 s^{2}$ core of nitrogen and the $1 s^{2} 2 s^{2} 2 p^{6}$ core of sulfur. The double $\zeta$ basis set described by Clementi and Roetti was employed. ${ }^{20}$

## Results and Discussion

Synthesis of $\mathrm{PPN}^{+} \mathbf{S}_{4} \mathbf{N}^{-}$. Salts of the $\mathrm{S}-\mathrm{N}$ anions, $\mathrm{S}_{3} \mathrm{~N}_{3}{ }^{-}$and $\mathrm{S}_{4} \mathrm{~N}_{5}{ }^{-}$, with small cations, e.g., alkali metals, exhibit a tendency to explode when subjected to mild pressure or heat. ${ }^{12,15}$ Even $n-\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{S}_{4} \mathrm{~N}_{5}^{-}$exploded when heated to $100^{\circ} \mathrm{C} .^{21}$ The dark blue, oily product ( $\lambda_{\max } 588 \mathrm{~nm}$, in DMF) was not characterized. ${ }^{21}$ We have, therefore, prepared salts of these anions with PPN $^{+}$, a cation noted for its ability to stabilize large, strongly nucleophilic metal carbonyl anions. ${ }^{22}$ The salts obtained, $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}_{5}^{-}$(1) and PPN ${ }^{+} \mathrm{S}_{3} \mathrm{~N}_{3}{ }^{-}$(2), are much safer to handle than salts with smaller cations and have allowed us to study the thermolysis of these recently discovered $\mathrm{S}-\mathrm{N}$ anions.

When a solution of $\mathbf{1}$ is heated to reflux in acetonitrile for 24 h , a gradual color change from yellow through green to very deep blue is observed. The final product is $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$obtained as dark blue crystals with a metallic copper-like lustre. If the thermolysis is stopped immediately after the initial appearance of the blue color ( $6-7 \mathrm{~h}$ ), and the solution is cooled to $-10^{\circ} \mathrm{C}$, crystals of $\mathbf{2}$ can be obtained. In a separate experiment it was shown that the transformation $\mathbf{2} \rightarrow \mathbf{3}$ takes place in refluxing acetonitrile.

$$
\underset{1}{\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}_{5}{ }^{-} \xrightarrow{-\mathrm{N}_{2} \mathrm{~S}} \mathrm{PPN}^{+} \mathrm{S}_{3} \mathrm{~N}_{3}-{ }_{2}^{-\mathrm{N}_{2},+\mathrm{S}^{0}} \mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}}
$$

This sequence of events is depicted in Figures 1 and 2. The

Figure 1. UV-visible spectra as a function of time for the transformation $\mathrm{S}_{4} \mathrm{~N}_{5}^{-}\left(\lambda_{\max } 293 \mathrm{~nm}\right) \rightarrow \mathrm{S}_{3} \mathrm{~N}_{3}^{-}\left(\lambda_{\max } 365 \mathrm{~nm}\right) \rightarrow \mathrm{S}_{4} \mathrm{~N}^{-}\left(\lambda_{\max } 582 \mathrm{~nm}\right)$, starting from a solution of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}_{5}^{-}\left(\right.$ca. $5.0 \times 10^{-2} \mathrm{M}$ ) in acetonitrile.

Figure 2. UV-visible spectra as a function of time for the transformation $\mathrm{S}_{3} \mathrm{~N}_{3}^{-}\left(\lambda_{\text {max }} 365 \mathrm{~nm}\right) \rightarrow \mathrm{S}_{4} \mathbf{N}^{-}\left(\lambda_{\text {max }} 582 \mathrm{~nm}\right)$, starting from a solution of $\mathrm{PPN}^{+} \mathrm{S}_{3} \mathrm{~N}_{3}^{-}$(ca. $5.0 \times 10^{-2} \mathrm{M}$ ) in acetonitrile.
structures of $\mathbf{S}_{4} \mathrm{~N}_{5}^{-13}$ and $\mathrm{S}_{3} \mathrm{~N}_{3}{ }^{-23}$ are known and that of $\mathbf{S}_{4} \mathrm{~N}^{-}$ is described in this paper. Although we have no direct evidence, the first step appears to involve loss of the neutral molecule $\mathrm{N}_{2} \mathrm{~S}$ from the $\mathrm{S}_{4} \mathrm{~N}_{5}-$ cage to give the six-membered $\mathrm{S}_{3} \mathrm{~N}_{3}$ - ring. The existence of $\mathrm{N}_{2} \mathrm{~S}$ has been postulated, ${ }^{24 \mathrm{a}}$ and ab initio MO calculations favor a linear, unsymmetrical structure, ${ }^{24 b}$ but no confirmatory experimental evidence for this molecule has been reported. Elemental sulfur is certainly produced in the thermolysis, presumably by disproportionation of $\mathbf{N}_{2} \mathrm{~S}$, and it is interesting to note that HFS-SCF calculations for $\mathrm{S}_{4} \mathbf{N}_{5}^{-}$show that introduction of bridging $\mathrm{N}^{-}$unit into the $\mathrm{S}_{4} \mathrm{~N}_{4}$ framework causes considerable weakening of the $\mathrm{S}-\mathrm{N}$ framework bonds. ${ }^{25}$ Thus, these theoretical results provide a possible rationale for the facile loss of $\mathrm{N}_{2} \mathrm{~S}$ from $\mathrm{S}_{4} \mathrm{~N}_{5}-$. The second step may also involve the initial loss of $\mathrm{N}_{2} \mathrm{~S}$

${ }^{a}$ Positional and thermal parameters for the hydrogen atoms can be found in the supplementary material. ${ }^{b}$ The form of the anisotropic thermal parameter is $\exp \left\{-\left[B_{11} h^{*} h^{*}+B_{22} k^{*} k^{*}+B_{33} l^{*} l^{*}+B_{12} h^{*} k^{*}+B_{13} h^{*} l^{*}+B_{23} k^{*} l^{*}\right]\right\}$.
from $\mathrm{S}_{3} \mathrm{~N}_{3}^{-}$to produce the hypothetical $\mathrm{S}_{2} \mathrm{~N}^{-}$ion, which would then react with sulfur to give $\mathrm{S}_{4} \mathrm{~N}^{-}$. Such a mechanism cannot be confirmed, since the well-defined isosbestic point in the transformation of $\mathrm{S}_{3} \mathrm{~N}_{3}$ to $\mathrm{S}_{4} \mathrm{~N}^{-}$(see Figure 2) precludes appreciable concentrations of any intermediate species. However, we have noted that solutions of $\mathrm{S}_{4} \mathrm{~N}^{-}$in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ do slowly revert to $\mathrm{S}_{3} \mathrm{~N}_{3}{ }^{-}$and sulfur (at room temperature). Here again it is difficult to envisage such a process occurring except through an intermediate anion, e.g., $\mathrm{S}_{2} \mathrm{~N}^{-}$. We are currently exploring this problem.

Crystal Structure of $\mathrm{PPN}^{+} \mathbf{S}_{4} \mathbf{N}^{-}$. The positional and thermal parameters for $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$are given in Table I. Figure 3 shows ORTEP plots of the cation and anion of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$together with the atomic numbering scheme. Bond lengths and bond angles are summarized in Table II. The X-ray structure determination reveals that the $\mathrm{S}_{4} \mathrm{~N}^{-}$anion has an unbranched cis, trans chain structure with nitrogen as the central atom, in contrast to the branched-chain structure found for the isoelectronic $\mathrm{CS}_{4}{ }^{2-}$ ion. ${ }^{10}$ The $\mathrm{S}_{4} \mathrm{~N}^{-}$chain is essentially planar, the maximum deviation from the least-squares plane through all five atoms being $0.046 \AA$ for $N(1)$ (Table III). As a result of the orientation of the $S(3)-S(4)$ bond, the $S(2)-S(4)$ distance ( $3.14 \AA$ ) is significantly shorter than the van der Waals separation ( $3.7 \AA$ ) for two sulfur atoms, but the HFS-SCF calculations described below indicate that there is no net bonding interaction between these two atoms. Other intramolecular contacts of interest in the $\mathrm{S}_{4} \mathrm{~N}^{-}$anion are $\mathrm{S}(2)-\mathrm{S}(3)$
$=2.773(2), \mathrm{S}(1)-\mathrm{N}(1)=2.856(5)$, and $\mathrm{S}(4)-\mathrm{N}(1)=2.918(5)$ $\AA$. The S-S bond lengths in $\mathrm{S}_{4} \mathrm{~N}^{-}$of 1.879 (3) and, to a lesser extent, 1.943 (2) $\AA$ are remarkably short compared to the corresponding distances in $\mathrm{S}_{5}{ }^{2-}, d(\mathrm{~S}-\mathrm{S}) \sim 2.06 \AA,{ }^{26}$ and $\mathrm{CS}_{4}{ }^{2-}$, $d(\mathrm{~S}-\mathrm{S})=2.02 \AA,{ }^{10}$ and suggest significant multiple-bond character, particularly for the $\mathbf{S}(3)-S(4)$ bond. The shortest known S -S bonds, apart from excited states in $\mathrm{S}_{2},{ }^{27}$ are $1.828 \AA$ in $\mathrm{S}_{2} \mathrm{I}_{4}{ }^{2+},^{28} 1.860 \AA$ in $\mathrm{S}=\mathrm{SF}_{2}{ }^{29}$ and $1.882 \AA$ in $\mathrm{S}_{2} \mathrm{O}{ }^{30}$ Short terminal sulfur-sulfur bonds $[d(\mathbf{S}-\mathbf{S}) \sim 1.91 \AA]$ have also been found for the open-chain derivative $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSN}=\mathrm{S}=\mathrm{S}^{31}$ and a related compound containing the $-\mathrm{SN}=\mathrm{S}=\mathrm{S}$ unit. ${ }^{32}$

An unusual feature of the structure of $\mathrm{S}_{4} \mathrm{~N}^{-}$is the marked asymmetry of the central SNS unit, $\mathrm{S}(3)-\mathrm{N}(1)=1.667$ (5) and $\mathrm{S}(2)-\mathrm{S}(1)=1.521(5) \AA$. The shorter $\mathrm{S}-\mathrm{N}$ bond is adjacent to the longer $S-S$ bond, but the angles at $S(2)$ and $S(3)$ are equal ( $\sim 110^{\circ}$ ) within experimental error. The observation of alternating

Figure 3. ORTEP plots for (a) the $\mathrm{S}_{4} \mathrm{~N}^{-}$anion and (b) the $\mathrm{PPN}^{+}$cation in $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$.
$\mathrm{S}-\mathrm{N}$ bond lengths in $\mathrm{S}-\mathrm{N}$ compounds is not unprecedented, e.g., $\mathrm{S}_{4} \mathrm{~N}_{4} \mathrm{~F}_{4}{ }^{33}$ and $\mathrm{S}_{4} \mathrm{~N}_{4}{ }^{2+} .{ }^{34}$ The origins of this alternation in $\mathrm{S}_{4} \mathrm{~N}^{-}$ will be discussed later, but it is worth stressing that the energy difference between equal and unequal $\mathrm{S}-\mathrm{N}$ bonds is likely to be small. For example, one of the forms of the $\mathrm{CS}_{4}{ }^{2-}$ ion found in $\mathrm{K}_{2} \mathrm{CS}_{4} \cdot \mathrm{CH}_{3} \mathrm{OH}$ shows two distinct $\mathrm{C}-\mathrm{S}$ bond lengths of 1.745 and $1.659 \AA$, while the other form shows essentially equivalent $\mathrm{C}-\mathrm{S}$ bonds. ${ }^{10}$

The P-N distances of 1.573 (3) and 1.562 (3) $\AA$ and the bond angle of 143.1 (2) ${ }^{\circ}$ at nitrogen in the $\mathrm{PPN}^{+}$cation are not unusual. ${ }^{35}$ A pair of stereoscopic drawings of the unit cell of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$are depicted in Figure 4. They clearly show how the bulky PPN ${ }^{+}$cation protects the relatively small $\mathrm{S}_{4} \mathrm{~N}^{-}$anion. A table of intermolecular contacts up to $3.75 \AA$ reveals no significant interactions (see supplementary material).

Vibrational Spectra of the $\mathbf{S}_{4} \mathbf{N}^{-}$Ion. In an earlier publication, ${ }^{8 b}$ tentative vibrational assignments for the $\mathrm{S}_{4} \mathrm{~N}^{-}$ion were made on the basis of a branched-chain structure by analogy with the isoelectronic $\mathrm{CS}_{4}{ }^{2-}$ ion, ${ }^{9,10}$ As a result of this X-ray structural determination, it is now clear that those assignments were incorrect. With particular reference to the assignment of vibrational frequencies to the two different $\mathrm{S}-\mathrm{S}$ bonds in $\mathrm{S}_{4} \mathrm{~N}^{-}$, we have recorded the infrared and Raman spectra of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$and $\mathrm{PPN}^{+} \mathrm{S}_{4} * \mathrm{~N}^{-}$(where ${ }^{*} \mathrm{~N}=30 \%{ }^{15} \mathrm{~N}$ ). The spectra are shown in Figures 5 and 6 and the observed vibrational frequencies and their assignments are summarized in Table IV. On the basis of correlations between S-S stretching frequencies and bond

[^5]

Figure 4. Stereoscopic drawings of unit cell of $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$.

Figure 5. Difference infrared spectrum of $\mathrm{PPN}^{+} \mathrm{Cl}^{-}$and $\mathrm{PPN}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$in acetonitrile solutions. Bands marked with an asterisk are those of the $\mathrm{S}_{4} \mathbf{N}^{-}$anion. Other peaks and inflections are due to imperfect cancellation of solvent and cation bands.

Figure 6. Solid-state (powder) Raman spectrum of $\mathrm{PPN}^{+} \mathrm{S}_{4} * \mathrm{~N}^{-}$obtained with $457.9-\mathrm{nm}$ excitation. Bands marked with an asterisk are not observed in the Raman spectrum of PPN ${ }^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$.
lengths, ${ }^{27,36}$ it seems likely that the strong bands observed at ca. 592 and $565 \mathrm{~cm}^{-1}$ in the infrared and Raman spectra of $\mathrm{S}_{4} \mathrm{~N}^{-}$

Figure 7. Bond parameters ( $\AA$ and deg) used in calculations of various conformations of $\mathrm{S}_{4} \mathrm{~N}^{-}$. The cis and trans designations refer to the geometry of an $\mathrm{S}-\mathrm{S}$ bond with respect to the remote $\mathrm{S}-\mathrm{N}$ bond.
correspond to the two S-S stretching vibrations. This assignment is confirmed by the observation that these two bands do not exhibit satellites due to ${ }^{15} \mathrm{~N}$ in the vibrational spectra of $\mathrm{PPN}^{+} \mathrm{S}_{4} * \mathrm{~N}^{-}$ (Figure 6). Thus the band at $592 \mathrm{~cm}^{-1}$ is assigned to the stretching mode of the shorter $\mathbf{S}-\mathbf{S}$ bond ( $\mathbf{S}(3)-\mathbf{S}(2)$ ) while the lower frequency band at ca. $565 \mathrm{~cm}^{-1}$ is ascribed to a similar vibration of $\mathbf{S}(1)-\mathbf{S}(2)$. The relatively high intensity of these bands in the infrared spectrum (Figure 5) is presumably a result of the high polarity of these $\mathrm{S}-\mathrm{S}$ bonds (vide supra). Two bands are observed above $600 \mathrm{~cm}^{-1}$ in the infrared and Raman spectra of $\mathrm{S}_{4} \mathrm{~N}^{-}$. The higher frequency band at $892 \mathrm{~cm}^{-1}$ is weak in both the infrared and Raman spectra while the band at $710 \mathrm{~cm}^{-1}$ is of medium intensity in the infrared and very strong in the Raman spectrum (the latter was obscured by solvent and/or cation bands in the spectra of $n-\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{S}_{4} \mathrm{~N}^{-3 b}$ ). The relatively high frequencies of these two bands suggest that they involve stretching of NS bonds and this assignment is confirmed by the observation of ${ }^{15} \mathrm{~N}$ satellites for these bands in both the infrared and Raman spectra

a Vibrational bands marked with an asterisk showed satellite bands resulting from the presence of ${ }^{15} \mathrm{~N}$ in the spectra of $\mathrm{PPN}^{+} \mathrm{S}_{4}{ }^{*} \mathrm{~N}^{-}$. ${ }^{\circ}$ Using CsI windows. ${ }^{c}$ In a KBr cell. ${ }^{d}$ Tentatively assigned to a bending mode involving the internal sulfurs as the central atoms.
(Figure 7). The observed frequency shifts are $17\left(891-\mathrm{cm}^{-1}\right.$ band) and $14 \mathrm{~cm}^{-1}$ ( $710-\mathrm{cm}^{-1}$ band). These shifts compare to 21 and $16 \mathrm{~cm}^{-1}$ calculated for two-center SN vibrations at 891 and 710 $\mathrm{cm}^{-1}$, and $23 \mathrm{~cm}^{-1}$ for a three-center SNS antisymmetric stretch at $891 \mathrm{~cm}^{-1}$. Although the isotopic shifts certainly confirm the involvement of the sulfur-bonded nitrogen in the bands at 710 and $891 \mathrm{~cm}^{-1}$, they do not allow ready distinction between the three-center SNS and two-center SN vibrations. One might reasonably attribute the 892 - and $710-\mathrm{cm}^{-1}$ bands to the stretching modes of the short and long SN bonds, respectively. However, the substantially different intensities of these two bands, despite the rather similar calculated polarities of the SN bonds, make this assignment questionable. The resonance Raman spectra are
of some assistance in this connection for it is known that, normally, a three-center symmetric stretching vibration is strongly enhanced. In our case (with exciting lines of 488 and 514.5 nm ) we find that the band at $710 \mathrm{~cm}^{-1}$ is increased in intensity, whereas that at $891 \mathrm{~cm}^{-1}$ is not. This suggests that the band at $710 \mathrm{~cm}^{-1}$ represents a vibrational mode with strong characteristics of the symmetric SNS stretch, whereas that at $891 \mathrm{~cm}^{-1}$ has more the characteristics of the antisymmetric stretch. (We might add that the enhanced intensity of the $710-\mathrm{cm}^{-1}$ band in the resonance Raman spectra also confirms the involvement of the SNS fragment for, as will be argued below, the optical transition is to a molecular orbital, $\Psi_{16}$, which is strongly associated with the nitrogen and the internal sulfur centers.)

Our assignment of the vibrational bands gains some support from the observation of bands at $906 \mathrm{w}, 712 \mathrm{vs}$, and $583 \mathrm{~s} \mathrm{~cm}^{-1}$ in the IR spectrum of $\mathrm{Ph}_{3} \mathrm{P}=$ NSNSS,,${ }^{16,31}$ in which the average $\mathrm{S}-\mathrm{N}$ bond length is $1.59 \AA$ (cf. $1.59 \AA$ in $\mathrm{S}_{4} \mathrm{~N}^{-}$). The strong band at $585 \mathrm{~cm}^{-1}$ in the Raman spectrum of $\mathrm{Ph}_{3} \mathrm{P}=$ NSNSS can be assigned to the S-S stretching vibration ( $d(\mathbf{S}-\mathbf{S})=1.908 \AA$ ).

Two other bands were observed in the vibrational spectra of $\mathrm{S}_{4} \mathrm{~N}^{-}$above $200 \mathrm{~cm}^{-1}$. A weak band at $416 \mathrm{~cm}^{-1}$ only appeared in the infrared spectrum and did not exhibit a ${ }^{15} \mathrm{~N}$ satellite in the spectrum of $\mathrm{PPN}^{+} \mathrm{S}_{4} * \mathrm{~N}^{-}$. The Raman band at $227 \mathrm{~cm}^{-1}$ was too weak and broad to detect the presence or absence of a ${ }^{15} \mathrm{~N}$ satellite band. The assignments of these two bands have not been confirmed, but they are likely to be bending modes.

Electronic Structure and Bonding in $\mathbf{S}_{4} \mathbf{N}^{-}$. Valence bond structures, such as those depicted below, do not give an adequate representation of the electronic distribution in $\mathrm{S}_{4} \mathrm{~N}^{-}$. We have therefore carried out ab initio HFS-SCF calculations for $\mathrm{S}_{4} \mathrm{~N}^{-}$

in order to obtain an MO description of the ground-state electronic structure. In an attempt to rationalize the experimentally observed geometry, we have carried out calculations for the following conformations of $\mathrm{S}_{4} \mathrm{~N}^{-}$: (a) experimental cis,trans (CTX), (b) symmetrical cis, trans (CT), and (c) symmetrical trans,trans (TT). These conformations and the bond parameters used in the calculations are shown in Figure 7.

Figure 8 displays the overlap populations and charge densities calculated for the various conformations of $\mathrm{S}_{4} \mathrm{~N}^{-}$. As expected, the nitrogen atom in the experimental conformation, CTX, carries a significant negative charge ( -0.35 ); the terminal sulfurs, however, carry a larger negative charge ( -0.42 and -0.44 ), while the internal sulfurs bear a small positive charge $(+0.01$ and +0.20$)$. Such charge alternation is typical of open-chain sulfur systems, e.g., sulfanes, ${ }^{37}$ and is accentuated in $\mathrm{S}_{4} \mathrm{~N}^{-}$by the central presence of an electronegative nitrogen atom. The relatively high intensity of the S-S stretching bands in the infrared spectra of $\mathrm{S}_{4} \mathrm{~N}^{-}$salts (vide supra and ref 3 b and 8 b ) is undoubtedly a consequence of the polarity of the S-S bonds. The overlap populations found for the $\mathrm{S}-\mathrm{N}$ linkages ( 0.53 and 0.55 ), cf. 0.52 for $\mathrm{S}_{3} \mathrm{~N}_{3}{ }^{-23}$, suggest a relatively strong $\mathrm{S}-\mathrm{N}$ bond. The relative magnitude of the $\mathrm{S}-\mathrm{S}$ overlap populations is the opposite of that expected on the basis of the observed bond lengths. This inversion of overlap populations is retained in an HFS ( $\mathrm{X}_{\alpha}$ ) calculation with the much less diffuse single $\zeta$ basis and is also observed in the results obtained by using the GaUSSIAN 76 ( $4-31 \mathrm{G}$ basis) HF procedure. In this connection it should also be pointed out that the overlap populations for the CT conformation are 0.77 and 0.64 , essentially the same as for the CTX conformation despite the equality of the $S-S$ bond lengths in the former. For the TT conformation the overlap population for both S-S linkages is 0.74 . It can be concluded that the inversion of overlap is more a reflection of the cis, trans conformation than of relative bond lengths.
A more detailed analysis of the bonding and charge distribution in $\mathrm{S}_{4} \mathrm{~N}^{-}$can be extracted from the orbital overlap populations given in Table V and from a knowledge of the symmetry of the various orbitals. Thus, we partiton the MOs into three groups: the $\pi$ orbitals, the $\sigma$ orbitals, and the nonbonding or lone-pair orbitals. Although desirable, such a classification can only be approximate since a given orbital may have several characteristics; e.g., it may be bonding with reference to one linkage and, yet, antibonding for another.
With the above cautionary statements we begin by noting that the orbitals $\psi_{7}, \psi_{10}, \psi_{12}, \psi_{15}$, and the LUMO, $\psi_{16}$, are $\pi$ orbitals; i.e., $\mathrm{S}_{4} \mathrm{~N}^{-}$is an $8 \pi$-electron system. The lowest of these orbitals, $\psi_{7}$ and $\psi_{10}$, are bonding ( $\pi$ ) whereas the HOMO, $\psi_{15}$, and the LUMO, $\psi_{16}$, are antibonding ( $\pi^{*}$ ). The intermediate orbital, $\psi_{12}$, functions as a weak $\pi$ bond for the S-S linkages and as a lone pair for nitrogen. More precisely, $\psi_{7}$ and $\psi_{16}$ are $\pi$ and $\pi^{*}$, respectively, for the S-N linkages while $\psi_{10}, \psi_{12}$, and $\psi_{15}$ mainly contribute to the S-S linkages. From the entries in the fourth column of Table V , which gives the orbital overlap population averaged over the two $\mathrm{S}-\mathrm{N}$ linkages, we note that the net $\pi$-type overlap population is $4 \times 0.06=0.24$ while from the fifth column we see that the net $\pi$-type overlap population averaged over the $\mathrm{S}-\mathrm{S}$ linkages is $4(0.01+0.05+0.03-0.07)=0.08$. These overlap populations correspond approximately to a half $\pi$ bond for each $\mathrm{S}-\mathrm{N}$ unit and less than a quarter $\pi$ bond for the $\mathrm{S}-\mathrm{S}$ units.

Figure 8. Overlap populations in brackets and atomic charges in parentheses for various conformations of $\mathrm{S}_{4} \mathrm{~N}^{-}$.

Let us now consider the $\sigma$-bonding framework. From column 4 in Table V we see that the orbitals $\psi_{1}, \psi_{2}, \psi_{4}$, and $\psi_{8}$ make significant $\sigma$-bonding contributions to the S-N linkage, whereas $\psi_{5}$ and $\psi_{11}$ are antibonding in this region. The net $\sigma_{\mathrm{SN}}-$ type overlap population of $4(0.08+0.03+0.04+0.03-0.04-0.06)=0.32$ corresponds to roughly a two-thirds $\sigma$ bond for each SN region. Referring to the fifth column of Table V, for the SS regions, we see that $\psi_{2}$ and $\psi_{3}$ make significant $\sigma$-bonding contributions while $\psi_{1}, \psi_{4}$, and $\psi_{11}$ make small bonding contributions and this total is reduced by the antibonding contributions of $\psi_{5}$. The net $\sigma_{\text {ss }}$-type overlap population of $4(0.07+0.07+0.01+0.01+0.02-0.03)$ $=0.60$ corresponds to roughly five-quarters of a $\sigma_{\text {SS }}$ bond. Taking the $\sigma$ and $\pi$ components of the bonding together, the $\mathrm{S}-\mathrm{N}$ linkages can be thought of as approximately $(2 / 3 \sigma+1 / 2 \pi)$ bonds, while the S-S linkages are approximately $(5 / 4 \sigma+1 / 4 \pi)$ bonds.

From the last four columns of Table $V$ it is easy to see that $\psi_{6}, \psi_{13}$, and $\psi_{14}$ each contribute lone-pair electrons to the terminal sulfurs, whereas $\psi_{9}$ plays a similar role for, primarily, the internal sulfurs. In addition $\psi_{12}$ provides some lone-pair character to both the terminal and the internal sulfurs. From the fifth last column of Table V we see that, as well as being antibonding, $\psi_{11}$ also provides lone-pair character to the nitrogen region. The charge buildup around nitrogen and the sulfur centers is, of course, due in part to these lone-pair electrons, but it must be remembered that much of this charge is due to the bonding and antibonding orbitals which are also associated with these centers.

We now turn to the interactions between nonbonded centers, particularly $S(2)-S(4)$, for which the experimental separation is $3.14 \AA$. These two centers are much closer together in the CT conformations of $\mathrm{S}_{4} \mathrm{~N}^{-}$than they would be in the TT conformation. An analysis of the overlap populations given in Table $V$ reveals that the $S(4)$ lone-pair distributions from $\psi_{13}$ and $\psi_{14}$ do interact significantly with $\mathrm{S}(2)$. However, the resulting overlap population, which is bonding (0.027) for $\psi_{13}$, is essentially canceled by an antibonding $(-0.025)$ contribution from $\psi_{14}$. It appears, therefore, that the apparent stability of the CTX conformation cannot be rationalized in terms of this "long-bond" interaction. However,
we should point out that the charge distribution obtained for the experimental conformation is more favorable than that which we find for the TT conformation. For example, as Figure 8 shows, the large negative charge $(-0.42)$ of the terminal sulfur $S(4)$ is relatively close to a significant positive charge ( +0.20 ) on the internal sulfur $S(2)$. The larger positive charges on the internal sulfurs in the CTX conformation can also stabilize the very negative nitrogen center. In the case where $S(3)$ and $S(4)$ are trans to the $\mathrm{N}-\mathrm{S}(2)$ linkage our calculations show that the internal sulfurs carry only very small positive charges ( 0.03 ); hence, one would expect less stabilization of the large negative charges on the nitrogen and terminal sulfur centers.

The visible spectrum of the $\mathrm{S}_{4} \mathrm{~N}^{-}$ion exhibits an intense absorption at ca. 580 nm . The transition-state method, suggested by Slater, ${ }^{40}$ is commonly used as an approximation to the theoretical value for this transition. In the present case, for a spinrestricted transition state, this procedure yields a value of 680 nm . However, the sum method, shown by Ziegler et al. ${ }^{41}$ to be a better approximation, yields a value of 610 nm , which is quite close to the experimental value of 580 nm . The calculation of the transition moments by the $\mathrm{X} \nabla$ method, evaluated for the HFS procedure by Trsic et al., ${ }^{42}$ yields a transition moment for the $\psi_{15} \rightarrow \psi_{16}$ (i.e., $\pi^{*} \rightarrow \pi^{*}$ ) transition, which is of order $10^{3}$ greater than that calculated for the $\psi_{14} \rightarrow \psi_{16}$ (i.e., $n \rightarrow \pi^{*}$ ) transition. Consequently, it would appear that the strong absorption observed at 580 nm is a HOMO $\pi^{*} \rightarrow$ LUMO $\pi^{*}$ transition.

The calculated statistical energies of the three conformations are within $10 \mathrm{kcal} \mathrm{mol}^{-1}$ of one another and one might therefore expect that the details of the conformation of the $\mathrm{S}_{4} \mathrm{~N}^{-}$ion will depend on the nature of the counterion. In particular, it seems possible that a conformation which more closely resembles the symmetrical CT conformation might be found in another salt of $\mathrm{S}_{4} \mathrm{~N}^{-}$. In this connection, we refer to the well-established existence of two forms of trihalide ions, e.g., $\mathrm{I}_{3}{ }^{-38}$ which is symmetrical in the $\mathrm{Ph}_{4} \mathrm{As}^{+}$salt but unsymmetrical in the $\mathrm{Cs}^{+}$and $\mathrm{NH}_{4}^{+}$ions. Furthermore, while bulky cations appear to favor the symmetrical form, it is not only cation size which influences the symmetry of the anion. For example, $\mathrm{Et}_{4} \mathrm{~N}^{+} \mathrm{I}_{3}{ }^{-}$has been shown to contain two structural modifications, one containing symmetrical and the other unsymmetrical $\mathrm{I}_{3}{ }^{-}$ions. ${ }^{39}$ The synthetic route to $\mathrm{S}_{4} \mathrm{~N}^{-}$salts described in this paper is applicable to salts with other cations and hence should provide an opportunity to test this suggestion.

Note Added in Proof: In a recent X-ray structure determination of $\mathrm{Ph}_{4} \mathrm{As}^{+} \mathrm{S}_{4} \mathrm{~N}^{-}$the $\mathrm{S}-\mathrm{N}$ bond lengths were found to be $\mathrm{S}(2)-\mathrm{N}(1)$ $=1.62$ and $\mathrm{S}(3)-\mathrm{N}(1)=1.56 \AA$ (A. W. Cordes and P. Swepston, private communication).

Acknowledgments. The authors are grateful to the Natural Sciences and Engineering Council of Canada and to the University of Calgary for financial support. Particular thanks are extended to Dr. M. Extine, Molecular Structure Corp., Texas, for the X-ray structure determination and to Dr. R. Kydd for helpful discussions and measurement of the Raman spectra. The use of $X_{\alpha}$ routines developed by T. Ziegler and by E. J. Baerends and co-workers is also acknowledged.

Supplementary Material Available: A listing of structure factor amplitudes, a table of the positional and thermal parameters used for the hydrogen atoms, and a table of intermolecular contacts up to $3.75 \AA$ ( 27 pages). Ordering information is given on any current masthead page.
