Just Accepted

"Just Accepted" manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides "Just Accepted" as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. "Just Accepted" manuscripts appear in full in PDF format accompanied by an HTML abstract. "Just Accepted" manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). "Just Accepted" is an optional service offered to authors. Therefore, the "Just Accepted" Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the "Just Accepted" Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these "Just Accepted" manuscripts.

Resistance in Gram-negative bacteria to β -lactam drugs is mediated primarily by the expression of β -lactamases and co-dosing of β -lactams with a β -lactamase inhibitor (BLI) is a clinically proven strategy to address resistance. New β -lactamases that are not impacted by existing BLIs are spreading and creating the need for development of novel broader spectrum BLIs. IID572 is a novel broad spectrum BLI of the diazabicyclooctane (DBO) class that is able to restore the antibacterial activity of piperacillin against piperacillin/tazobactam-resistant clinical isolates. IID572 is differentiated from other DBOs by its broad inhibition of β -lactamases, and the lack of intrinsic antibacterial activity.

Keywords: β-lactamase inhibitors, diazabicyclooctane, DBOs, piperacillin, antibiotic.

Multidrug-resistant (MDR) Gram-negative bacteria are increasing in prevalence in many regions of the world and present a threat to the health care system, especially in the hospital. Treatment of infections caused by these pathogens still relies in large part on the use of β -lactam antibiotics ¹. Resistance in Gram-negative bacteria to β lactam antibiotics is mediated primarily through the expression of β -lactamases, which degrade the β -lactam ². Extended spectrum serine β -lactamases (ESBLs) are spreading and cause resistance to penicillins, cephalosporins and monobactams. Physicians are therefore relying increasingly on carbapenems, which are stable to ESBLs, but this now appears to be driving the global spread of organisms producing carbapenemases ³.

β-Lactamase-mediated resistance can in principle be addressed through the development of novel β-lactams with increased stability against β -lactamases⁴, or by codosing with a β -lactamase inhibitor (BLI). The approved BLIs clavulanic acid, sulbactam and tazobactam have become limited in their clinical usefulness, because they 52 are not effective inhibitors of ESBLs or class C serine β-53 lactamases (cephalosporinases) and are not active 54 against serine carbapenemases such as Klebsiella 55 pneumoniae carbapenemases (KPCs). Although 56 piperacillin/tazobactam (TZP) is still a very important 57 broad-spectrum hospital drug, the BLI tazobactam does 58

not effectively protect piperacillin against ESBLs and serine carbapenemases. As a consequence, the proportion of clinical strains expressing ESBLs or carbapenemases that are susceptible to TZP is moderate (60%) and low (0.3%) respectively according to a recent study 5 .

Recently avibactam, a novel BLI of the diazabicyclooctane (DBO) class (Figure 1) was launched in combination with ceftazidime (CZA), addressing serine B-lactamase mediated resistance in Enterobacteriaceae and Pseudomononas aeruginosa⁶. However, CZA has a narrower spectrum than TZP, lacking coverage of methicillin-susceptible Staphylococcus aureus and of anaerobes ^{7, 8}. Avibactam is a broad spectrum BLI, providing coverage of ESBLs, serine carbapenemases, class C enzymes and some class D β -lactamases. However, emergence of resistance in the clinic upon treatment of carbapenem-resistant Enterobacteriaceae (CREs) with CZA has been reported ^{9, 10}, and it is currently not clear what the extend of this vulnerability is and if other DBO BLIs in the pipeline will show similar development of resistance upon treatment¹¹. In addition to their BLI activity, the DBOs zidebactam, nacubactam, ETX-2514 and to some extent avibactam are inhibitors of penicillin binding protein 2 (PBP-2) and exert antibacterial activity against some Gram-negative organisms ¹²⁻¹⁵. PBP-2 inhibition by

these DBOs acts synergistically with PBP-3-inhibitory β -lactams ¹⁶. However, *in vitro*, reduced susceptibility to the antibacterial activity of PBP-2 inhibitors, including DBOs, is selected at high frequency via a multiplicity of mutations related to the stringent response and it is not clear at this point if this will translate into rapid resistance development in the clinic ¹². Another concern with BLIs that show intrinsic antibacterial activity is that the use of minimal inhibitory concentrations (MICs) for the combinations with β -lactams as a biomarker to predict efficacy is not straight-forward, owing to multiple modes of actions for efficacy and potential differences in PK/PD for both partners.

We initiated a program aiming to discover novel DBOs with improved properties. Our initial goal was to identify novel DBOs with clinically-relevant intrinsic antibacterial activity due to inhibition of multiple PBPs as we hypothesized that inhibition of multiple PBPs would reduce the frequency of selecting single-step mutants of the stringent response associated with earlier DBOs which inhibit PBP-2 only, following the original vision of chemists at Hoechst Marion Roussel¹⁷. Fortuitously, we identified a DBO that was a very potent BLI, providing broad inhibition of serine β -lactamases, but that did not engage PBP-2 and correspondingly lacked intrinsic antimicrobial activity altogether. Our vision for this BLI was for it to replace tazobactam in combination with piperacillin, to restore broad activity of piperacillin against drug-resistant Enterobacteriaceae.

RESULTS AND DISCUSSION

Chemistry. The preparation of DBOs is challenging, due to long and linear synthetic routes and the high ring strain of the diazabicyclooctane scaffold 18, 19 leading to instability towards nucleophiles. Therefore, we chose to access novel analogs of DBOs through late stage modification, which has the advantage of divergent synthetic routes for more efficient analoging. Our initial strategy was to utilize the alpha/beta unsaturated ester 6 (Scheme 1) for accessing 3-substituted analogs, which had not been explored much in the literature, in part probably due to the synthetic difficulties. Conventional Michael additions to 6 failed to give the desired products, resulting instead in opening of the cyclic urea moiety. However, radical Michael additions via visible light-mediated photo-redox catalysis ²⁰ proved successful, leading to the diastereomeric methylene amino-substituted analogs 7-10 in 79% overall yield (Scheme 1). Boc-deprotection of the amino group with TFA in 7 resulted in cyclization, providing after neutralization the lactam 11. No lactam formation was observed for isomers 8-10 following similar treatment. Formation of the lactam was initially not intended, however, we were interested to profile a final compound with this novel structural feature. The benzyl group in 11 was removed by hydrogenation and a sulfonyl group was introduced using SO₃/pyridine to give **12**. Because

of the low overall yield of **12** from **5** of only 0.1%, we subsequently designed a more efficient and scalable route for **12**, which we intend to published elsewhere.

Since 12 showed an interesting profile as a β -lactamase inhibitor (discussed in the next section), we prepared a number of analogs, including those with substitutions on the amide, as well as the corresponding six-membered lactam, the synthesis of which is described in the patent ²¹. These analogs were synthetically more complex than 12, with similar properties to 12 in early profiling and are therefore not discussed in this report.

Hydrolytic stability. The chemical hydrolytic stability of **12** was determined in phosphate buffer pH 7.4 at 37 °C and was found to be similar to other DBOs ($t_{1/2} = 55$ h, Table 1). As a point of reference, the carbapenem imipenem and the monobactam aztreonam show a $t_{1/2}$ of 46 h and >2000 h respectively in this assay ⁴. Since DBOs are hydrolytically labile, similar to carbapenems, care must be taken to ensure sufficient chemical solution stability of analogs for development and for biological assays.

Intrinsic antibacterial activity for 12 and reference DBOs. Antibacterial activity was determined by broth microdilution assay following the recommended CLSI methodology ²² against quality control strains of E. coli, K. pneumoniae and P. aeruginosa (Table 1). Avibactam showed weak antibacterial activity against E. coli and K. pneumoniae, whereas nacubactam and zidebactam showed stronger antibacterial activity against E. coli and for the latter also against P. aeruginosa, in agreement with reports in the literature ²³⁻²⁵. As discussed above, the antibacterial activity observed for some DBOs is a result of selective PBP-2 inhibition, a feature that selects for high frequencies of resistance in vitro. Compound 12 did not show measurable antibacterial activity against any of the isolates tested (MICs $>64 \mu g/mL$), similar to relebactam²⁶.

Potentiation of piperacillin by compound 12 against strains expressing β -lactamases. Potentiation of piperacillin by 12 in the presence of a wide range of serine β -lactamases was determined using isogenic strains of *E. coli* expressing individual β -lactamases

60

 from a multi-copy plasmid ³. Comparative data Were generated for the BLIs taxobactam, avibactam, relebactam and vaborbactam ²⁷. MICs for piperacillin/ BLI combinations were determined with a fixed concentration of BLI at 4 µg/mL. Vaborbactam was tested at 8 µg/mL, relebactam at 2 µg/mL, tentatively reflecting the relative high and low human doses and exposures for vaborbactam ²⁸ and relebactam ²⁹ prespectively (Tables 2 and S1). Piperacillin is a substrate for all four classes of β-lactamases, the serine β-lactamases classes A, C and D, as well as the metallo β-lactamases (class B, Table S1), as apparent from the large shift of the MIC against strains expressing β-lactamases relative to the parental strain. Tazobactam did not effectively potentiate piperacillin in the presence of KPCs, TEM-1, BEL-1 and OXA-type enzymes, Apparent from the elvated MICs for strains expressing these enzymes. A smaller MIC shift is observed for tazobactam and the class C enzymes AmpC and P99, indicating sub-optimal inhibition by tazobactam. This is also reflected in the clinic, where TEM-1 hyper production, as well as AmpC upregulation and OXA enzymes have been associated with elvated MICs for TZP against clinical strains ³⁰, which often express multiple of these β-lactamases. Tazobactam's inability to inhibit KPC-2 is probably at least in part due to tazobactam being a substrate for KPC-2 ³¹. Piperacillin/ relebactam showed elevated MICs for strains expressing CTX-M-15, TEM-10, SHV-12 and all OXAs, indicating the limitations for relebactam to inhibit class A enzymes was also observed for activity against Class D enzymes. A similar profile of activity against Class D enzymes was also observed for activity against Class D enzymes was also observed for activity against Class D enzymes. A similar profile of activity against Class D enzymes was also observed for activity against Class D enzymes. A similar profile of activity against Class D enzymes was also observed for		
 generated for the BLIs tazobactam, avibactam, relebactam and vaborbactam ²⁷. MICs for piperacillin/ BLI combinations were determined with a fixed concentration of BLI at 4 µg/mL. Vaborbactam was tested at 8 µg/mL, relebactam at 2 µg/mL, tentatively reflecting the relative high and low human doses and exposures for vaborbactam ²⁸ and relebactam ²⁹ respectively (Tables 2 and S1). Piperacillin is a substrate for all four classes of β- lactamases, the serine β-lactamases classes A, C and D, as well as the metallo β-lactamases (class B, Table S1), as apparent from the large shift of the MIC against strains expressing β-lactamases relative to the parental strain. Tazobactam did not effectively potentiate piperacillin in the presence of KPCs, TEM-1, BEL-1 and OXA-type enzymes, apparent from the elevated MICs for strains expressing these enzymes. A smaller MIC shift is observed for tazobactam and the class C enzymes AmpC and PO9, indicating sub-optimal inhibition by tazobactam. This is also reflected in the clinic, where TEM-1 hyper production, as well as AmpC upregulation and OXA enzymes have been associated with elevated MICs for TZP against clinical strains ³⁰, which often express multiple of these β-lactamases. Tazobactam's inability to inhibit KPC-2 is probably at least in part due to tazobactam being a substrate for KPC-2 ³¹. Piperacillin/ relebactam showed elevated MICs for strains expressing CTX-M-15, TEM-10, SHV-12 and all OXAs, indicating the limitations for relebactam to inhibit class A enzymes other than KPCs and its lack of activity against class D enzymes. A similar profile of	1	from a multi-copy plasmid ⁴ . Comparative data were
 relebactam and vaborbactam ²⁷. MICs for piperacillin/ BLI combinations were determined with a fixed concentration of BLI at 4 µg/mL. Vaborbactam was tested at 8 µg/mL, relebactam at 2 µg/mL, tentatively reflecting the relative high and low human doses and exposures for vaborbactam ²⁸ and relebactam ²⁹ respectively (Tables 2 and S1). Piperacillin is a substrate for all four classes of β- lactamases, the serine β-lactamases classes A, C and D, as well as the metallo β-lactamases (class B, Table S1), as apparent from the large shift of the MIC against strains. Tazobactam did not effectively potentiate piperacillin in the presence of KPCs, TEM-1, BEL-1 and OXA-type enzymes, apparent from the elevated MICs for strains expressing these enzymes. A smaller MIC shift is observed for tazobactam and the class C enzymes AnpC and O99, indicating sub-optimal inhibition by tazobactam. This is also reflected in the clinic, where TEM-1 hyper production, as well as AmpC upregulation and OXA enzymes have been associated with elevated MICs for TZP against clinical strains ³⁰, which often express multiple of these β-lactamases. Tazobactam's inability to inhibit KPC-2 is probably at least in part due to tazobactam being a substrate for KPC-2 ³¹. Piperacillin/ relebactam showed elevated MICs for strains expressing CTX-M-15, TEM-10, SHV-12 and all OXAs, indicating the limitations for relebactam to inhibit class A enzymes other than KPCs and its lack of activity against class D enzymes. A similar profile of narrow spectrum inhibition of class A and lack of activity against class D enzymes. However, the lack of	1	generated for the BLIs tazobactam, avibactam,
 BLI combinations were determined with a fixed concentration of BLI at 4 μg/mL. Vaborbactam was tested at 8 μg/mL, relebactam at 2 μg/mL, tentatively reflecting the relative high and low human doese and exposures for vaborbactam ²⁸ and relebactam ²⁹ respectively (Tables 2 and S1). Piperacillin is a substrate for all four classes of β- lactamases, the serine β-lactamases (class B, Table S1), as well as the metallo β-lactamases (class B, Table S1), as a apparent from the large shift of the MIC against strains expressing β-lactamases relative to the parental strain. Tazobactam did not effectively potentiate piperacillin in the presence of KPCs, TEM-1, BEL-1 and OXA-type enzymes, apparent from the elevated MICs for strains expressing these enzymes. A smaller MIC shift is observed for tazobactam and the class C enzymes AmpC and OYA enzymes have been associated with elevated MICs for TZP against clinical strains ³⁰, which often express multiple of these β-lactamases. Tazobactam's inability to inhibit KPC-2 is probably at least in part due to tazobactam being a substrate for KPC-2 ³¹. Piperacillin/ relebactam showed elevated MICs for strains expressing CTX-M-15, TEM-10, SHV-12 and all OXAs, indicating the limitations for relebactam to inhibit class A enzymes other than KPCs and its lack of activity against Class D enzymes. A similar profile of activity against OXA carbapenemase, Hick OXA-48, limits the utility of these combinations to carbapenemases of the class A type (mainly KPCs). Our data also show that these BLIs are not able to effectively potentiate a β-lactam thas is nore labile to serine β-<td>2</td><td>relebactam and vaborbactam²⁷. MICs for piperacillin/</td>	2	relebactam and vaborbactam ²⁷ . MICs for piperacillin/
 bit containing the elements of the probability of the probab	3	BLI combinations were determined with a fixed
concentration of BL1 at 4 μg/mL. Vaporactam was tested at 8 μg/mL, relebactam at 2 μg/mL, tentatively reflecting the relative high and low human doses and exposures for vaborbactam ²⁸ and relebactam ²⁹ respectively (Tables 2 and S1). Piperacillin is a substrate for all four classes of β- lactamases, the serine β-lactamases classes A, C and D, as well as the metallo β-lactamases (class B, Table S1), as apparent from the large shift of the MIC against strains expressing β-lactamases relative to the parental strain. Tazobactam did not effectively potentiate piperacillin in the presence of KPCs, TEM-1, BEL-1 and OXA-type enzymes, apparent from the elevated MICs for strains expressing these enzymes. A smaller MIC shift is observed for tazobactam and the class C enzymes AmpC and P99, indicating sub-optimal inhibition by tazobactam. This is also reflected in the clinic, where TEM-1 hyper production, as well as AmpC urgegulation and OXA enzymes have been associated with elevated MICs for TZP against clinical strains ³⁰ , which often express multiple of these β-lactamases. Tazobactam's inability to inhibit KPC-2 is probably at least in part due to tazobactam being a substrate for KPC-2 ³¹ . Piperacillin/ relebactam showed elevated MICs for strains expressing CTX-M-15, TEM-10, SHV-12 and all OXAs, indicating the limitations for relebactam to inhibit class A enzymes other than KPCs and its lack of activity against class D enzymes. A similar profile of narrow spectrum inhibition of class A and lack of activity against OXA carbapenemases like OXA-48, imits the utility of these combinations to carbapenemases of the class A type (mainly KPCs). Our data also show that these BLIs are not able to effectively potentiate a β-lactam that is more labile to serine β- lactamase sthan a carbapenem, like piperacillin. Avibactam has been reported to have a broader spectrum of β-lactamase inhibitory activity, resulting in better protection against class A, with some coverage of class A so enzymes, especially OXA-48 ³² , and our d	4	DEI comonations were determined with a fixed
 tested at 8 μg/mL, relebactam at 2 μg/mL, tentatively reflecting the relative high and low human doses and exposures for vaborbactam ²⁸ and relebactam ²⁹ respectively (Tables 2 and S1). Piperacillin is a substrate for all four classes of β- lactamases, the serine β-lactamases classes A, C and D, as well as the metallo β-lactamases (class B, Table S1), as apparent from the large shift of the MIC against strains expressing β-lactamases relative to the parental strains. Tazobactam did not effectively potentiate piperacillin in the presence of KPCs, TEM-1, BEL-1 and OXA-type enzymes, apparent from the elevated MICs for strains expressing these enzymes. A smaller MIC shift is observed for tazobactam and the class C enzymes AmpC and P99, indicating sub-optimal inhibition by tazobactam. This is also reflected in the clinic, where TEM-1 hyper production, as well as AmpC upregulation and OXA enzymes have been associated with elevated MICs for TZP against clinical strains ³⁰, which often express multiple of these β-lactamases. Tazobactam's inability to inhibit KPC-2 is probably at least in part due to tazobactam being a substrate for KPC-2 ³¹. Piperacillin/ relebactam showed elevated MICs for strains expressing CTX-M-15, TEM-10, SHV-12 and all OXAs, indicating the limitations for relebactam to inhibit class A enzymes other than KPCs and its lack of activity against class D enzymes. A similar profile of narrow spectrum inhibition of class A and lack of activity against class D enzymes was also observed for vaborbactam and vaborbactam are intended for use in combination with carbapenems, which are relatively stable to most serine β-lactamases. However, the lack of activity against class D enzymes was also observed	5	concentration of BLI at 4 μ g/mL. vaborbactam was
reflecting the relative high and low human doses and exposures for vaborbactam ²⁸ and relebactam ²⁹ respectively (Tables 2 and S1). Piperacillin is a substrate for all four classes of β- lactamases, the serine β-lactamases classes A, C and D, as well as the metallo β-lactamases (class B, Table S1), as apparent from the large shift of the MIC against strains expressing β-lactamases relative to the parental strain. Tazobactam did not effectively potentiate piperacillin in the presence of KPCs, TEM-1, BEL-1 and OXA-type enzymes, apparent from the elevated MICs for strains expressing these enzymes. A smaller MIC shift is observed for tazobactam and the class C enzymes AmpC and P99, indicating sub-optimal inhibition by tazobactam. This is also reflected in the clinic, where TEM-1 hyper production, as well as AmpC upregulation and OXA enzymes have been associated with elevated MICs for TZP against clinical strains ³⁰ , which often express multiple of these β-lactamases. Tazobactam's inability to inhibit KPC-2 is probably at least in part due to tazobactam biourg a substrate for KPC-2 ³¹ . Piperacillin/ relebactam showed elevated MICs for strains expressing CTX-M-15, TEM-10, SHV-12 and all OXAs, indicating the limitations for relebactam to inhibit class A enzymes other than KPCs and its lack of activity against class D enzymes. A similar profile of narrow spectrum inhibition of class A and lack of activity against class D enzymes. A similar profile of the activity against class D enzymes. A similar profile of activity against class D enzymes. A similar profile of the activity against class D enzymes, which are relatively stable to most serine β-lactamases. However, the lack of activity against class D enzymes, which are relatively stable to most serine β-lactamases. However, the lack of activity against class D enzymes, which are relatively stable to most serine β-lactamases. However, the lack of activity against class D enzymes, which are relatively stable to most serine β-lactamases. However, the lack of act	5	tested at 8 μ g/mL, relebactam at 2 μ g/mL, tentatively
7exposures for vaborbactam 28 and relebactam 298respectively (Tables 2 and S1).10Piperacillin is a substrate for all four classes of β-11lactamases, the serine β-lactamases classes A, C and D,13as apparent from the large shift of the MIC against14strains expressing β-lactamases relative to the parental15strain.16Tazobactam did not effectively potentiate piperacillin in17the presence of KPCs, TEM-1, BEL-1 and OXA-type18enzymes, apparent from the elevated MICs for strains19expressing these enzymes. A smaller MIC shift is20observed for tazobactam and the class C enzymes AmpC21and P99, indicating sub-optimal inhibition by22tazobactam. This is also reflected in the clinic, where23TEM-1 hyper production, as well as AmpC upregulation24and OXA enzymes have been associated with elevated25minibit KPC-2 is probably at least in part due26to tazobactam being a substrate for KPC-2 ³¹ .27piperacillin/ relebactam showed elevated MICs for31strains expressing CTX-M-15, TEM-10, SHV-12 and all26OXAs, indicating the limitations for relebactam to31inhibit class A enzymes other than KPCs and its lack of32activity against class D enzymes was also observed for34stable to most serine β-lactamases. However, the lack of35activity against class D enzymes was also observed for36activity against class D enzymes was also observed for37	6	reflecting the relative high and low human doses and
8ccsposites involved values and S1).9respectively (Tables 2 and S1).10Piperacillin is a substrate for all four classes of β-11lactamases, the serine β-lactamases classes A, C and D,12as well as the metallo β-lactamases (class B, Table S1),13as apparent from the large shift of the MIC against14strains expressing β-lactamases relative to the parental15strain.16Tazobactam did not effectively potentiate piperacillin in17the presence of KPCs, TEM-1, BEL-1 and OXA-type18enzymes, apparent from the elevated MICs for strains19expressing these enzymes. A smaller MIC shift is20observed for tazobactam and the class C enzymes AmpC21and P99, indicating sub-optimal inhibition by22tazobactam. Carbamylation and decarbamylation kinetics against CTX-M-15 and KPC-2 β-lactamases. DBOs cause carbamylation of the active site serine of β-lactamases. with reversible but slow decarbamylation ³³⁻³⁵. The kinetic constants for carbamylation of the enzymes CTX-M-15 and KPC-2 by compound 12 and avibactam were determined using a stopped-flow spectrophotometric assay following nitrocefin (NCF) substrate hydrolysis (see supplementary methods). The values for the carbamylation efficiencies k_2/K_i of avibactam for CTX-M-15 and KPC-2 were 5.9±2.6 x 10^5 M⁻¹s⁻¹ and 7.2±3.6 x 10^4 M⁻¹s⁻¹ respectively (Table 3), similar to the values reported by Ehmann et al 36 (1.3) x 10^5 M⁻¹s⁻¹ and 1.3 x 10^4 M⁻¹s⁻¹ respectively). Compound 12 showed \sim 32- and 7- fold higher carbamylation efficiencies than avibactam with CTX-M-15 and KPC-2 respectively. It is possible that the fused five-membered lactam ring in compound 12 exerts additional ring strain on the cyclic urea warhead in 12, leading to a higher reactivity of the cyclic urea moiety towards the active site serine of these β -lactamases. Both avibactam and especially **12** appear to carbamylate CTX-M-15 faster than KPC-2. The residence times of binding for compound 12 to CTX-M-15 and KPC-2 were 12 and 36 minutes respectively, shorter than those observed for avibactam (33 and 152 minutes). It is possible that the strain through the lactam moiety in the adduct of 12 to the β -lactamase is leading to higher offrates. However, we have not vet confirmed the structure of the adduct between 12 and CTX-M-15 and KPC-2, so it is also conceivable that 12 may react with the active site serine of β -lactamases through ring opening of the five membered lactam. We have not confirmed reversibility for the inhibition of β -lactamases by 12, so it is also possible that **12** is not re-generated upon cleavage from the β -lactamases, but is hydrolyzed. Further studies are needed to elucidate the mechanism of inhibition of β -lactamases by **12**, and to understand the impact of mechanism and kinetics on human dose selection.

Potentiation of piperacillin by compound 12 against clinical strains. *In vitro* activity of piperacillin and compound 12 against 190 TZP-non-susceptible clinical isolates of Enterobacteriaceae was determined by broth microdilution, with 12 tested at a fixed concentration of 4 µg/mL (Tables 4 and S2). Annotated mechanisms of resistance for the strains included de-repressed class C enzymes, KPCs, upregulated TEM-1, ESBLs like SHV-5 and -7, as well as OXA-48-like enzymes. This panel did not include metallo– β -lactamase producing strains. Potentiation of piperacillin by 12 was observed for the majority of the strains, with MIC_{50/90} values of 8/ 16 µg/mL respectively for the combination, representing

broad susceptibility of most of the TZP-resistant strains, based on the approved breakpoint for TZP of 16 µg/mL. Exceptions, aside from metallo- β -lactamase expressing strains which were not investigated here, were several OXA-181 or CTX-M-15/CMY-42 expressing strains of E. coli from Turkey, Thailand and the Philippines (supplementary Table S3). According to our isogenic panel studies, compound 12 inhibits these β -lactamases, suggesting that there may be additional β -lactamases that are not inhibited by compound 12, or that non- β lactamase mediated mechanisms that decrease susceptibility to PIP (or compound 12) are present in these isolates. Consistent with the latter, we found that these isolates harbored an alteration of the *ftsI* gene encoding a YRIN insertion in the target of PIP, (PBP-3 ³⁷) that was previously shown to impact susceptibility to aztreonam ³⁸ and LYS228 ³⁹. We showed that an *E. coli* ATCC25922 derivative harboring the YRIN insertion (or a previously described YRIK insertion ³⁸ was also 4fold less susceptible to PIP than ATCC 25922 (MIC shifting from 4 μ g/mL to 16 μ g/mL, supplementary Table S4). Therefore these insertions directly reduce susceptibility to PIP via a target-based mechanism that would not be overcome by the BLI activity of compound **12**. It is possible that other non- β -lactamase mechanisms of resistance are also be present in these isolates. The impact of PBP-3 alteration on susceptibility to PIP/12 found here is reminiscent of a recent report implicating a TIPY insertion in PBP-3 in reducing susceptibility of a carbapenem resistant E. coli clinical isolate to ceftazidime, ceftaroline or aztreonam in combination with avibactam 40.

32 The activity of PIP/12 against clinical strains of the 33 anaerobic species Bacteroides fragilis group, 34 methicillin-susceptible Staphylococcus aureus (MSSA), 35 Pseudomonas aeruginosa and Haemophilus. influenzae 36 isolates was determined as well (Table 5). PIP/12 was 37 equipotent compared to TZP against B. fragilis group, P. 38 aeruginosa and H. influenzae isolates, and 2-fold more 39 potent than TZP against MSSA (piperacillin is not active 40 against methicillin-resistant S. aureus (MRSA), due to 41 changes in the target PBP2a⁴¹, which cannot be rescued 42 by addition of a BLI). Thus the combination of PIP/12 43 has the potential for empiric broad coverage, including 44 the treatment of drug-resistant Enterobacteriaceae. 45

Pharmacokinetics of compound 12 in preclinical

species. Pharmacokinetic parameters for **12** were determined in mouse, rat and dog. Data in rat were also generated for avibactam for comparison (Table 6). The profile of **12** was similar to other DBOs and β -lactams in all species, showing low clearance with a significant portion of the dose being recovered unchanged in urine

in rat and dog. Plasma protein binding of 12 was low to moderate for all preclinical species and 23% for human. The clearance of **12** in rat was somewhat lower than clearance determined for avibactam (9.7 vs 18 mL/min/kg respectively), however the doses for 12 and avibactam were different and the values close, so the difference may not be significant. Clearance for avibactam in rat has been reported in the literature as 24 mL/min/kg⁴². Clearance for **12** in dog was lower than the reported value for avibactam ⁴³ (2.3 vs 6.1 mL/min/kg respectively). The half-life for 12 in rat was longer than for typical β -lactams (6.2 h), due to a long $t_{1/2} \beta$. If the relative low clearance observed for 12 in rat and dog is also observed in man, then this may lower the dose requirement for 12, without risk of accumulation in q4 dosing typically used for piperacillin.

Efficacy of PIP/12 in the murine thigh infection model. The combination of compound 12 with piperacillin was profiled for efficacy in the neutropenic mouse thigh infection model (Table 7). We chose the same ratio for PIP:BLI as for TZP (8:1) for this study. However the human dose prediction has not been performed yet and may indicate a different ratio for optimal efficacy. We chose a relatively resistant strain of K. pneumoniae expressing KPC-11 and SHV-12 for this experiment. The MIC for TZP against this strain was $>64 \,\mu\text{g/mL}$, higher than the clinical breakpoint for TZP of 16 µg/mL. At the doses administered, TZP did not achieve efficacy against this strain in this model, consistent with the elevated MIC and the presence of a KPC β -lactamase, which is not inhibited by tazobactam. PIP/12 was efficacious against this strain, consistent with the lower MIC of 16 µg/mL reflecting inhibition of class A β -lactamases including KPCs by 12.

Conclusions. Compound **12** is a potent and broad spectrum β -lactamase inhibitor that does not inhibit PBP-2 and lacks measureable intrinsic antibacterial activity. This may remove potential development and therapeutic liabilities attributed to selective PBP-2 inhibition. Compound **12** effectively protects piperacillin against degradation by serine β -lactamase-expressing drug-resistant Enterobacteriaceae and other organisms, restoring activity against the majority of TZP-resistant strains tested. The pharmacokinetic parameters for **12** were evaluated in rodents and dog and found to be similar to avibactam, except for **12** having a longer half life, especially in dog. PIP/ **12** but not TZP showed efficacy against a KPC-expressing strain of *K*. *pneumoniae* in the murine thigh infection model.
