This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard <u>Terms & Conditions</u> and the <u>Ethical guidelines</u> still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

# Pictet-Spengler condensations using 4-(2-aminoethyl)coumarins

Vitaliy M. Sviripa, <sup>\*a,b,c</sup> Michael V. Fiandalo, <sup>d</sup> Kristin L. Begley, <sup>b,e</sup> Przemyslaw Wyrebek, <sup>b,e</sup> Liliia M. Kril, <sup>b,e</sup> Andrii G. Balia, <sup>b,e</sup> Sean R. Parkin, <sup>f</sup> Vivekanandan Subramanian, <sup>g</sup> Xi Chen, <sup>h</sup> Alexander H. Williams, <sup>a</sup> Chang-Guo Zhan, <sup>a,b</sup> Chunming Liu, <sup>c,e</sup> James L. Mohler, <sup>d,i</sup> and David S. Watt, <sup>b,c,e</sup>

Androgen-deprivation therapy (ADT) is only a palliative measure, and prostate cancer invariably recurs in a lethal, castrationresistant form (CRPC). Prostate cancer resists ADT by metabolizing weak, adrenal androgens to growth-promoting 5 $\alpha$ dihydrotestosterone (DHT), the preferred ligand for the androgen receptor (AR). Developing small-molecule inhibitors for the final steps in androgen metabolic pathways that utilize 17-oxidoreductases required probes that possess fluorescent groups at C-3 and intact, naturally occurring functionality at C-17. Application of the Pictet-Spengler condensation to substituted 4-(2-aminoethyl)coumarins and 5 $\alpha$ -androstane-3-ones furnished spirocyclic, fluorescent androgens at the desired C-3 position. Condensations required the presence of activating C-7 amino or N,N-dialkylamino groups in the 4-(2aminoethyl)coumarins component of these condensation reactions. Successful Pictet-Spengler condensation, for example, of DHT with 9-(2-aminoethyl)-2,3,6,7-tetrahydro-1H,5H,11H-pyrano[2,3-f]pyrido[3,2,1-ij]quinolin-11-one led to a spirocyclic androgen, (3R,5S,10S,13S,17S)-17-hydroxy-10,13-dimethyl-1,2,2',3',4,5,6,7,8,8',9,9',10,11,12,12',13,13',14,15,16,17docosahydro-7'H,11'H-spiro-[cyclopenta[a]phenanthrene-3,4'-pyrido[3,2,1-ij]pyrido[4',3':4,5]pyrano[2,3-f]quinolin]-5'(1'H)-one. Computational modeling supported the surrogacy of the C-3 fluorescent DHT analog as a tool to study 17oxidoreductases for intracrine, androgen metabolism.

inhibitors<sup>6</sup>

for

hydroxysteroid dehydrogenases7.

#### Introduction

Prostate cancer growth and progression rely on the activation of the androgen receptor (AR) by the circulating, testicular androgen, testosterone (T) or its intracellular metabolite, 5 $\alpha$ dihydrotestosterone (DHT), the preferred ligand for AR transactivation<sup>1-2</sup>. Men, who present with advanced prostate cancer or who fail potentially curative therapy, undergo androgen-deprivation therapy (ADT) intended to lower circulating testosterone levels, to deprive the AR of activating ligands and to induce cancer regression.<sup>3-4</sup> Unfortunately, androgen-deprivation therapy is only a temporary, palliative measure, since prostate cancer produces intratumoral

59 60 The "frontdoor" pathway converts the adrenal androgens, such as dehydroepiandrosterone and 4-androstene-3,17-dione (2), to testosterone (3) that subsequently undergoes  $\Delta^4$ -reduction to DHT (1). The "primary backdoor" pathway converts the penultimate  $5\alpha$ -androstane- $3\alpha$ ,  $17\beta$ -diol (4) directly to DHT<sup>12-16</sup> (1) without passing through testosterone (3) as an intermediate. The "secondary backdoor" pathway converts 4and rost ene-3, 17-dione (2) to  $5\alpha$ -and rost ane-3, 17-dione (5) that undergoes reduction of the C-17-keto group to  $DHT^{12, 14, 16-23}$  (1), also without passing through testosterone (3) as an One commonality among these pathways intermediate. involved C-17 redox reactions mediated bv the aldo/ketoreductase<sup>24-26</sup> (AKR1C3; HSD17B5) and 17Bhydroxysteroid dehydrogenase<sup>8</sup> (HSD17B3) for the conversion of 4-androstene-3,17-dione (2) to testosterone (3); the conversion of  $5\alpha$ -androstane-3,17-dione (5) to DHT (1); and the conversion of  $5\alpha$ -androstan- $3\alpha$ -ol-17-one (6) to  $5\alpha$ and rost ane-3 $\alpha$ , 17 $\beta$ -diol (4) (Fig. 1).

Our focus on developing small-molecule inhibitors for various 17-oxidoreductases, alone or in combination<sup>27</sup>, that perform these interconversions required fluorescent probes that had a C-3 fluorophore with excitation and emission patterns in the 550-650 nm range and that retained the intact, natural functionality at C-17. These combined challenges led us to select coumarins as fluorophores and to explore methodology for their attachment to the C-3 position of  $5\alpha$ -androstan-3ones<sup>28-30</sup>. We now report the scope of the Pictet-Spengler condensation<sup>31-34</sup> of C-7 amino-substituted 4-(2aminoethyl)coumarins with aldehydes and ketones, NMR and crystallography studies that established X-rav the diastereoselectivity in adducts derived from 5 $\alpha$ -androstan-3ones, the mechanism of these reactions and computational modeling of adducts in the active site of 17<sup>β</sup>-hydroxysteroid dehydrogenase type  $5^{35-36}$  (17 $\beta$ -HSD5; AKR1C3). Our findings auger well for the application of these probes in drug discovery.

#### Results

Variants of the Pechmann condensation<sup>37-38</sup> provided access to C-7 substituted 4-(2-aminoethyl)coumarins **9a-9e** for this study (**Scheme 1**). Specifically, the condensation of

aminoethyl)coumarin 9e (Scheme 1). The Pictet-Spengler condensations of coumarins 9a, 9b or 9e that possessed C-7 amino or C-7 N,N-dialkylamino groups with either acyclic and monocyclic ketones 10a-10f or 3-ketosteroids 10g-10k under acidic conditions afforded 1,2,3,4-tetrahydro-5Hchromeno[3,4-c]pyridin-5-ones 11 (Scheme 2A) in good yields (Table 1). For example, the condensation of coumarin 9e with  $5\alpha$ -androstan-17 $\beta$ -ol-3-one (DHT) (10i) afforded a single diastereomer of the spirocyclic, fluorescent adduct 11ei that was more compact than previously reported, bulky DHT analogs that possessed a linker between umbelliferone and 3β-amino- $5\alpha$ -androstan-17 $\beta$ -ol<sup>28</sup> or possessed a linker between fluorescein isothiocyanate and either a C-3 hydrazone or Ocarboxymethyloxime derivative of DHT<sup>29-30</sup>. The hygroscopic nature of some of the hydrochloride and trifluoroacetate salts of the adducts 11 necessitated their isolation as N-acetyl derivatives, as noted in Table 1.

Table 1. Synthesis conditions and yields of Pictet-Spengler adducts 11 formed from C-7 amino-substituted 4-(2-aminoethyl)coumarins 9 and ketones 10.

derivative; <sup>3</sup>isolated as hydrochloride salt; <sup>4</sup>isolated as a trifluoroacetate salt.

A range of steroidal and non-steroidal carbonyl compounds served to define the scope of these Pictet-Spengler reactions with coumarins 9 as illustrated by the condensation of 1methylpiperidin-4-one (10f) with 9b and the condensation of  $5\alpha\text{-androstan-}17\beta\text{-ol-}3\text{-one}$  (10i) with coumarins 9a and 9e (Scheme 2A). In general, condensations with unhindered ketones varying from acyclic to monocyclic ketones were successful in yields of 60-90% (Table 1). In contrast, the condensations of the coumarin 9e either with hindered ketones such as 5 $\alpha$ -androstan-17-one or with  $\alpha$ , $\beta$ -unsaturated ketones such as testosterone (3) were unsuccessful. This differential proved advantageous in the regiospecific reactivity modification of  $5\alpha$ -androstane-3,17-dione (10h) with coumarin 9e that led exclusively to the C-3 adduct 11eh in 57% yield. Contrary to a prior report of a successful Pictet-Spengler reaction of an amino-substituted coumarin with formaldehyde<sup>39</sup>, condensations of aldehydes with coumarins 9 led to poor yields of isolated products, presumably because of adventitious air-oxidation. Deliberate efforts to oxidize the intermediate 1,2,3,6-tetrahydropyridines from condensations with aldehydes led to poor yields of pyridines. For example, a Pictet-Spengler reaction of coumarin 9e with p-tolualdehyde followed by cupric bromide-catalyzed air oxidation<sup>40</sup> of the intermediate tetrahydropyridine 12 led to only a 20% yield of the 5H-chromeno[3,4-c]pyridin-5-one 13 (Scheme 2B).

#### ARTICLE

Confirmation of the C-3*R* stereochemical assignments in the spirocyclic DHT adduct **11ei** (**Scheme D2A**) **defiee Dot D4 Gefiee D5 Ge** 

**Fig. 2.** 2D ROESY spectrum of DHT analog **11ei**. Spectrum recorded using Agilent 400 MHz at 25°C. Dotted lines show region expanded that displays the NOE connectivity between  $NH_2^+$  and ring A protons (*i.e.*, H-5 (and H-1 overlapping), H-4, H-2, and  $CH_2$  adjoining  $NH_2^+$ ).

The Pictet-Spengler reactions of coumarins **9** and various ketones employed three different conditions that depended on the solubility of the ketone component and the desire, in the case of steroid condensations, to precipitate the products from acidic, ethanol solutions using water. A mixture of acetone-trifluoroacetic acid at reflux sufficed for reactions with acetone (condition A); trifluoracetic acid in dichloromethane at 25°C; (condition B) effected the condensations of **9** with monocyclic ketones **10b-10f**, and 1:10 concentrated hydrochloric acid in ethanol at reflux (condition C) promoted successful reactions with steroidal ketones **10g-10k** to give the desired adducts **11** (**Table 1**). Depending on conditions, the acid-catalyzed condensation of  $17\alpha$ -methyl- $5\alpha$ -androstan- $17\beta$ -ol-3-one (**10j**)

**Fig. 3.** Wagner-Meerwein Rearrangment. Panel A: Products of Pictet-Spengler condensation of coumarin **9e** and  $17\alpha$ -methyl- $5\alpha$ -androstan- $17\beta$ -ol-3-one (**10j**). Panel B: An ellipsoid plot (50% probability) for the single-crystal structure of rearrangement product (**14**). Hydrogen atoms were omitted to enhance clarity.

with coumarin **9e** led not only to the expected product **11ej** but also to a Wagner-Meerwein rearrangement<sup>43</sup> product **14** (**Fig. 3A**). 59 60 In the course developing small-molecule therapies for CRPC, we required fluorescent analogs for the androgens that appear in the penultimate, intratumoral pathways converging on  $5\alpha$ dihydrotestosterone (DHT). Specifically, we focused our interest on inhibitors for the 17-oxidoreductases that appear in three places in the late-stage metabolism of androgens to DHT, and we required fluorescent androgen probes with fluorescent groups at C-3 and natural functionality at C-17. The acidcatalyzed Pictet-Spengler reaction of coumarins 9a, 9b and 9e bearing C-7 amino or C-7 N,N-dimethylamino substituents with 3-ketosteroids, such as  $5\alpha$ -androstane-3,17-dione (10h) and  $5\alpha$ -androstan-17 $\beta$ -ol-3-one (10i), met these objectives and provided the adducts 11 with an intensely fluorescent, spirocyclic group attached at C-3 in good yield (Table 1). These reactions required either a 1:10 (v/v) mixture of trifluoroacetic acid and dichloromethane for ketones 10a-10f or a 1:10 (v/v) mixture of concentrated hydrochloric acid and absolute ethanol for steroidal ketones 10g-10k. A combination of sophisticated NMR experiments and an X-ray structure of a Wagner-Meerwein rearrangement<sup>43</sup> product 14 (Fig. 3) established the C-3R-diastereoselectivity of these reactions with steroid substrates. Similar Pictet-Spengler reactions, however, of coumarins 9c and 9d bearing C-7 hydroxyl or methoxy substituents, respectively, in place of C-7 amino substituents were unsuccessful. Likewise, extension of this Pictet-Spengler reaction to the condensations of coumarins 9 with aldehydes was largely unsuccessful, even after attempts to effect the deliberate oxidation of the intermediate adduct to a pyridine (Scheme 2B).

The classic Pictet-Spengler reaction<sup>31-32</sup> involved an acid-catalyzed condensation of activated 2-(1*H*-indol-3-yl)ethan-1-amine with

Fig. 4. Contrasting skeletons of key participants in Pictet-Spengler reactions.

either an aldehyde or a ketone to give an intermediate imminium salt and a subsequent cyclization  $\sqrt{a3}$  spinocoeffic intermediate to provide a substituted 2,3,4,9-tetrahydro-1*H*pyrido[3,4-*b*]indole. Superficially, the Pictet-Spengler reaction of coumarins **9** was a vinylogous extension of the classic reaction involving 3-(2-aminoethyl)-1*H*-indoles, as displayed in a skeletal format (**Fig. 4**), in which the iminium carbon linked to the  $\alpha$  carbon in the indole case and to the  $\zeta$ -carbon in the coumarin case.

A mechaism for these acid-catalyzed Pictet-Spengler reactions of coumarins **9a**, **9b** and **9e** with ketones **10** must take into account the following observations: [1] the requirement for highly acidic, aqueous conditions; [2] the rapid formation of the products from the intermediate, iminium salts derived from the condensation of the C-7 amino- or *N*,*N*-dialkylaminosubstituted coumarins **9a**, **9b** and **9e** with ketones **10**; and [3] the failure of the 7-hydroxy- and 7-methoxy substituted 4-(2aminoethyl)coumarins **9c** and **9d**, respectively, to participate in these reactions.

We propose a mechanism for the successful Pictet-Spengler condensations of C-7 amino-substituted 4-(2-aminoethyl)coumarins **9a**, **9b** and **9e** with ketones **10** that involves an initial, rapid condensation leading to an intermediate imine and a rate-determining cyclization to a tetrahydropyridine product **11**. For example, the acid-catalyzed condensation of coumarin **9e** with 5 $\alpha$ -androstan-17 $\beta$ -ol-3-one (**10i**) furnishes an intermediate, *biscationic* iminium ion **14a** (Scheme 3). The acidic conditions (est. pH 1) used for these

Scheme 3. Mechanism of Pictet-Spengler reactions of 4-(2-aminoethyl)coumarins 9 with ketones (10).

condensations and the calculated pK<sub>a</sub> values for 7-(*N*,*N*-dimethylamino)coumarin (pK<sub>a</sub> 3.48) and *N*-methylcyclohexanimine (pK<sub>a</sub> 10.14), using the ChemAxon software (version 19.18; ChemAxon, Inc., Cambridge, MA), support a biscationic structure involving protonation of both the imine and aniline moieties in **14a**. The agreement between calculated pK<sub>a</sub> values for *N*,*N*-dimethylaniline (pK<sub>a</sub> 5.02) and experimental values (pK<sub>a</sub> 5.06<sup>44</sup>-5.07<sup>45</sup>) supported the veracity of these calculated pK<sub>a</sub> values. This suggestion for a biscationic

#### Journal Name

species finds precedent a similar species generated from paminostyrene with strong acids having Hammett acidities H<sub>0</sub> greater than one<sup>46</sup>. In our case, protonation followed by tautomerization leads to the biscationic, enolic form of the coumarin **14b** that undergoes rate-limiting condensation to furnish the iminoquinone methide **14c**. Addition of the *si*-face of the enol to the  $\beta$ -face of the iminium ion in **14b** (*i.e.*, equatorial addition) produces an iminoquinone methide **14c** with C-3*R* and C-3'*R* stereochemistry. The alternative, *re*-face addition provides the C-3'S epimer but proceeds through a transition state that is more sterically hindered than that from the *re*-face based on MM2 calculations for the relative stability of the 3*R*,3'*R* and the 3*R*,3'*S* products. Final, irreversible deprotonation of **14c** at C-3' affords the observed product **11ei** (**Scheme 3**).

Heating the adduct **11ef** with tetrahydro-4*H*-thiopyran-4-one (**10e**) in dichloromethane-trifluoroacetic acid (condition B) for 3 days failed to provide any of the spirocyclic ketone-exchange product **11ee**. In summary, an electron-donating partner in the coumarin-based Pictet-Spengler reaction is a vinylogous analog of the indole partner in the classic Pictet-Spengler reaction. The activating C-7 amino substituent in the coumarin moiety **9e** counterbalances the deactivating carbonyl group and leads to a biscationic enol intermediate, such as **14b** (**Scheme 3**) that then leads to successful condensations. Analogous reactions of 4-(2aminoethyl)coumarins **9c** and **9d** (**Scheme 1**) that possess either a C-7 hydroxy or C-7 methoxy group fail to generate a bicationic enol intermediate and hence, fail to produce adducts **11** just as benzofuran cases fail in the classic Pictet-Spengler reactions.

Computational modeling of the binding of the fluorescent, spirocyclic adduct **11eh** in the ligand-binding domain of human 17 $\beta$ -hydroxysteroid dehydrogenase-5 (17 $\beta$ -HSD5) indicated that the compact nature of this fluorescent androgen **11eh** did not interfere with binding to the active site. The adduct **11eh** adopted the same pose as the naturally occurring ligand, 5 $\alpha$ - androstane-3,17-dione (**5**; **ASD**)<sup>35</sup> (**Fig. 5**).

**Fig. 5.** Computational modeling. Panel A: 5 $\alpha$ -Androstane-3,17-dione (5) in the SP1 binding site of AKR1C3 (PDB: 1XF0) containing proximal NADP<sup>+35</sup>. Panel B: Pictet-Spengler adduct (**11eh**) derived from 5 $\alpha$ -androstane-3,17-dione (5) in the SP1 binding site of AKR1C3 (PDB: 1XF0) containing proximal NADP<sup>+35</sup>.

ARTICLE

#### View Article Online DOI: 10.1039/D0NJ02664F

The BCD rings of **11eh** were inserted into the SP1 binding pocket in an identical fashion as seen for **5**, and the C-18 and C-19 angular methyl groups of **5** and **11ei** projected into the oxyanion hole of 17 $\beta$ -HSD5 bounded by Y55, H117 and NADP<sup>+</sup>. Hydrogen bonding with S129 further stabilizes the observed binding mode with **11eh**. These binding features indicated that the fluorescent ASD-based adduct **11eh** possessed a binding mode that matched that of ASD itself. In a similar fashion, the ASD adduct **11eh** occupied the same binding pocket seen for a previously described inhibitor, 3-carboxamido-1,3,5-(10)estratrien-*17R*-spiro-2-(5,5-dimethyl-6-oxo)tetrahydropyran (EM1404) that bound to17 $\beta$ -HSD5 (PDB:1ZQ5)<sup>36</sup>.

#### Conclusions

In summary, the Pictet-Spengler condensation of substituted 4-(2-aminoethyl)coumarins and ketones furnished fluorescent (4aS,14bS)-1,2,3,4,4a,8,9,12,13,14b-decahydro-5H,7H,11Hpyrido[3,2,1-ij]pyrido[4',3':4,5]pyrano[2,3-f]quinolin-5-ones. This work describes the scope of this variant of the Pictet-Spengler reaction with various coumarins, proposes a mechanism consistent with the substituents in the coumarin moiety, and defines the stereochemistry at C-3 in spirocyclic products derived from 3-ketosteroids by a combination of detailed NMR studies and an X-ray structure. Computational modeling supported the surrogacy of a C-3 fluorescent derivative of  $5\alpha$ -androstan-17 $\beta$ -ol-3-one as a tool to study 17oxidoreductases for intracrine, androgen metabolism in prostate cancer. Future studies will describe applications of these fluorescent androgens for image flow cytometry and will elucidate the effects of these fluorescent androgens on the prevention of prostate cancer growth promotion during ADT and on the stimulation of androgen receptor-regulated gene expression.

#### Experimental

Chemicals were purchased from Millipore Sigma (St. Louis, MO, USA) or Fisher Scientific (Hampton, NH, USA) or were synthesized according to literature procedures. Solvents were used from commercial vendors without further purification unless otherwise noted. Nuclear magnetic resonance spectra were acquired on a Varian (<sup>1</sup>H at 400MHz and <sup>13</sup>C at 100MHz or <sup>1</sup>H at 500MHz and <sup>13</sup>C at 125MHz) instruments. High resolution electrospray ionization (ESI) mass spectra were recorded on an LTQ-Orbitrap Velos mass spectrometer (Thermo Fisher Scientific, Waltham, MA, USA). The FT resolution was set at 100,000 (at 400 m/z). Samples were introduced through direct infusion using a syringe pump with a flow rate of 5µL/min. Purity of compounds was established using combustion analyses (Atlantic Microlabs, Inc. Norcross, GA, USA). Compounds were chromatographed on preparative layer Merck silica gel F254 (Fisher Scientific) plates unless otherwise indicated.

Methyl 3-Oxo-5-((2,2,2-trifluoroacetyl)amino)pentanoate (7). To a solution of 22.3 g (250 mmol) of  $\beta$ -alanine in 125 mL of methanol at 25°C was added 35 mL (250 mmol) of triethylamine. After 5 min, 37 mL (312 mmol, 1.25 eq) of ethyl trifluoroacetate was added, and the mixture was allowed to stir for 24 h at 25°C. The solvent was evaporated under reduced pressure, and the residue was diluted with 50 mL of H<sub>2</sub>O and acidified with concentrated hydrochloric acid. The mixture was extracted with ethyl acetate, and the combined organic layers were washed with brine and dried over anhydrous MgSO<sub>4</sub>. After filtration, the solvent was evaporated at reduced pressure to give 42.1 g (91 %) of 3-(2,2,2-trifluoroacetamido)propanoic acid<sup>47</sup> as a white solid: mp 114-116°C (lit<sup>47</sup> mp 114-116°C). <sup>1</sup>H NMR (400 MHz, DMSO-d<sub>6</sub>) δ 12.3 (s, 1H), 9.47 (br s, 1H), 3.42-3.3 (m, 2H), and 2.54-2.46 (m, 2H). <sup>13</sup>C NMR (100 MHz, DMSO $d_6$ )  $\delta$  172.5, 156.4 (q, <sup>2</sup>J<sub>CF</sub> = 35.7 Hz), 116 (q, <sup>1</sup>J<sub>CF</sub> = 286.9 Hz), 35.6, 32.8. A suspension of 3.08 g (32.3 mmol) of magnesium chloride and 7.2 g (46.2 mmol, 1.4 eq) of monomethyl monopotassium malonate in 45 mL of anhydrous THF was stirred for 4 h at 50°C under a nitrogen atmosphere. In a second flask, 6 g (37 mmol, 1.2 eq) of 1.1'-carbonyldiimidazole was added portionwise to a solution of 5.7 g (30.8 mmol) of 3-[(2,2,2trifluoroacetyl)amino]propanoic acid in 30 mL of anhydrous THF at 0-5°C. The mixture in the second flask was stirred for 1 h at 25°C and was added dropwise to the methylmagnesium malonate suspension at 25°C. The mixture was stirred for 16 h, concentrated, and diluted with ethyl acetate. The ethyl acetate solution was washed with saturated, aqueous NaHCO<sub>3</sub> solution and brine. After drying over anhydrous MgSO<sub>4</sub>, the mixture was filtered and concentrated. The product was chromatographed on silica gel using 2% methanol-dichloromethane to give 6.1 g of **7** as a colorless oil (82%). <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>)  $\delta$  7.13 (br s, 1H), 3.27 (s, 3H), 3.64-3.56 (m, 2H), 3.48 (s, 2H), 2.87 (t, J = 5.7 Hz, 2H).  $^{13}\text{C}$  NMR (100 MHz, DMSO-d\_6)  $\delta$  202.1, 167.4, 157.4 (q,  ${}^{2}J_{CF}$  = 37 Hz), 115.8 (q,  ${}^{1}J_{CF}$  = 287.6 Hz), 52.7, 48.8, 41.5, 34.5. ## 4-(p-Tolyl)-8,9,12,13-tetrahydro-5H,7H,11H-pyrido[3,2,1-

*ij*]pyrido[4',3':4,5]pyrano[2,3*-f*]quinolin-5-one (13). The procedure described under Condition B was repeated using 200 10 mg (0.62 mmol) of 9e and 0.29 mL (2.49 mmol) of 4-11 toluylaldehyde to afford crude 4-(p-tolyl)-1,2,3,4,8,9,12,13-12 octahydro-5H,7H,11H-pyrido[3,2,1-13

ij]pyrido[4',3':4,5]pyrano[2,3-f]quinolin-5-one 2,2,2trifluoroacetate in 58% yield. To 100 mg (0.2 mmmol) of this trifluoracetate salt in 6 mL of dimethyl sulfoxide was added 100 μL (0.7 mmol, 3.5 eq) of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) and 94 mg (0.42 mmol, 2.1 eq) of cupric bromide. The solution was stirred at 25°C for 16 h. The mixture was poured into 20 mL of aqueous ammonia solution (5% w/w) and extracted with ethyl acetate. The organic layers were washed with brine dried over anhydrous MgSO<sub>4</sub>, filtered and concentrated. The product was purified by chromatography using 1:50 methanol-dichloromethane (R<sub>f</sub> 0.26) to provide 15 mg (20%) of 13 as a yellow powder: mp 216-218°C. <sup>1</sup>H NMR (400 MHz, DMSO- $d_6$ )  $\delta$  8.67 (d, J = 5.6 Hz, 1H), 7.96 (d, J = 5.7 Hz, 1H), 7.73 (s, 1H), 7.38 (d, J = 8.1 Hz, 2H), 7.19 (d, J = 7.9 Hz, 2H), 3.31-3.22 (m, 4H), 2.79 (t, J = 6.3 Hz, 2H), 2.74 (t, J = 6.4 Hz, 2H), 2.37 (s, 3H), 1.9 (d, J = 6.8 Hz, 4H). <sup>13</sup>C NMR (101 MHz, DMSO-d<sub>6</sub>) δ 162.9, 158.91, 151.24, 149.32, 146.12, 144.32, 138.54, 137.33, 128.87, 127.89, 121.57, 118.18, 113.2, 110.85, 105.61, 102.94, 49.22, 48.67, 27.03, 20.96, 20.93, 20.07, 19.99. ## X-Ray Crystallography

X-ray diffraction data were collected at 90.0(2) K on a Bruker D8 Venture  $\kappa$ -axis diffractometer using MoK( $\alpha$ ) X-rays and using well-established, low-temperature crystal-handling techniques<sup>48</sup>. Raw data were integrated, scaled, merged and corrected for Lorentz-polarization effects using the APEX3 package (Bruker-AXS Inc., Madison, WI, US. Corrections for absorption were applied using SADABS<sup>49</sup>. The structure was solved by direct methods (SHELXT<sup>50</sup>) and refinement was carried out against F2 by weighted full-matrix least-squares (SHELXL<sup>50</sup>). Hydrogen atoms were found in difference maps placed at calculated positions and refined using riding models. Non-hydrogen atoms were refined with anisotropic displacement parameters. Absolute configuration was known due to the unchanging stereochemistry of the steroid ring Atomic scattering factors were taken from the system. International Tables for Crystallography. Experimental conditions, atomic coordinates, bond lengths and angles, as well as diffraction data and the crystallographic model were archived in the CIF, available free of charge from the Cambridge Crystallographic Data Centre (CCDC), structure code CCDC 1888376.

#### NMR Spectroscopy

DOI: 10.1039/D0NJ02664F NMR experiments were carried out at 25°C using DMSO-d<sub>6</sub> on an Agilent 400 MHz spectrometer using a 5 mm probe equipped with a z-gradient optimized for 1H detection. Chemical shifts were referenced relative to the residual protonated solvent signal set at 2.54 ppm<sup>51</sup>. A normal one-dimensional 1H and 13C (proton decoupled) and DEPT-135 (Distorsionless Enhancement of Polarization Transfer) spectra<sup>52</sup> were acquired and twodimensional homonuclear (<sup>1</sup>H-<sup>1</sup>H) correlation spectroscopy (COSY and ROESY)<sup>41-42</sup> 2D-heteronuclear correlations (<sup>1</sup>H-<sup>13</sup>C) spectra (HSQC and HMBC) were acquired using standard pulse sequences from the Agilent library. Spectral widths of 4340 Hz for both dimensions with 1024 complex data points in t2 and 256 *t*1 increments were used for ROESY and COSY experiments. The relaxation delay between successive pulse cycles was set to 1s and ROESY mixing time of 400 millisec was used. Forty transients for each increment were collected for ROESY, and 16 transients for each increment were collected for COSY experiments. Phase sensitive two-dimensional spectra were obtained using the time-proportional phase incrementation method (TPPI). Spectra were zero-filled to 2048x1024 real data points along f2 and f1, respectively. Sine-bell  $\pi/3$  window functions were used in both dimensions. HSQC adiabatic NMR spectrum was acquired with spectral widths of 4595 Hz (<sup>1</sup>H) and 20100 Hz (13C) with 1s of recycled delay to show direct 1H-13C connectivity and C-H correlation.

#### **Computational Modeling**

The X-ray structure<sup>35</sup> of the androgen-ligand binding domain in human  $17\beta$ -hydroxysteroid dehydrogenase type 5 (PDB: 1XF0) with  $5\alpha$ -androstane-3,17-dione was selected as the template to model the binding of the fluorescent adduct 11eh. The initial enzyme structure was downloaded from the RCSB Protein Data Bank and was subsequently prepared for docking via Autodock Tools.<sup>53</sup> The adduct **11eh** was docked using Autodock Vina<sup>54</sup> into the position occupied by  $5\alpha$ -androstane-3,17-dione in  $17\beta$ -HSD5. The binding poses of **11eh** obtained from Vina that contained high overlap with that of 11eh. The binding pose was further refined by performing a series of energy minimization processes. Briefly, the AMBER14SB force field<sup>55</sup> and the second generation of the general AMBER force field (gaff2) were used for the proteins and ligands, respectively. Partial charges for **11eh** were generated *via* the Antechamber<sup>56</sup> program in AMBER 18 using the AM1-BCC model.<sup>57</sup> Two courses of minimization were conducted using a hybrid protocol of twenty five-hundred steps of steepest descent minimization followed by a conjugate gradient minimization until a maximum twenty five-hundred iteration steps was reached or the convergence criterion (the root-mean-square of the energy gradient is less than  $1 \times 10-4$ kcal/mol·Å) was satisfied. During the first step of minimization, a force constant of 100 kcal/mol·Å2 was applied on the protein The second minimization step consisted of one atoms. thousand steps of steepest descent minimization, followed by fifteen hundred steps of conjugate gradient minimization, and this course of minimization had no restraints for either the ligand or the protein atoms.

Author contributions

James L. Mohler, Michael V. Fiandalo, Chunming Liu, Vitaliy M. Sviripa and David S. Watt conceived the overall experimental question, assisted with and contributed to the experimental design, and supervised data acquisition and analysis and manuscript preparation. Vitaliy M. Sviripa, Kristin L. Begley, Przemyslaw Wyrebek, Liliia Kril and David S. Watt planned and executed the synthetic chemistry. Vivekanandan Subramanian performed the 2D NMR studies. Sean R. Parkin performed the X-ray crystallography study. Xi Chen, Alexander H. Williams and Chang-Guo Zhan performed the  $pK_a$  calculations and the computational modeling studies. All authors reviewed the manuscript.

# **Conflicts of interest**

CL and DSW have partial ownership in a for-profit venture, Epionc, Inc., that seeks to develop small-molecule inhibitors for cancer treatment. In accord with University of Kentucky policies, CL and DSW have disclosed this work to the University of Kentucky's Intellectual Property Committee and to a Conflict of Interest Oversight Committee.

# Acknowledgements

VMS was aided in part by an institutional grant from the American Cancer Society (IRG-16-182-28). DSW was supported by NIH R01 CA172379, the Office of the Dean of the College of Medicine, the Markey Cancer Center, the Center for Pharmaceutical Research and Innovation (CPRI) in the College of Pharmacy, Department of Defense Idea Development Award PC150326P2, and NIH P20 RR020171 from the National Institute of General Medical Sciences (to L. Hersh). CL was supported by NCI (R01 CA172379). JLM was supported by NCI (P01 CA77739, P20 RR020171, R21 CA2051, and P30 GM110787); the Department of Defense (DoD Prostate Cancer Research Program Award W81XWH-16-1-0635 and Post-doctoral Training Award W81XWH-15-1-0409); the National Science Foundation for the D8 Venture diffractometer (MRI award CHE1625732); the Shared Instrument Award (NIH 1S10D018048); NCI research Specialist Award (R50CA211108) and the NCI Cancer Center Support Grant to Roswell Park Comprehensive Cancer Center (P30 CA016056) for the Flow and Image, Pathology Network, Biostatistics and Bioinformatics Shared Resources.
