## CONCLUSIONS

5-(Hydroxymethy1)-2,2,5-triphenyl-1,3,2,5-dioxaborataphosphoniarinane reacts with diphenylamine and o-aminobenzoic acid with the formation of 5-(aminomethyl)-2,2,5-triphenyl-1,3,2,5-dioxaborataphosphoniarinanes, whereas 1,5,3,7-diammoniadiphosphacyclooctanes are formed with m- and p-aminobenzoic acids. With o-aminobenzoic acid, hydroxymethylphosphines and hydroxymethylphosphonium salts give the corresponding aminomethylphosphines and aminomethylphosphonium salts.

ISOPRENYLATION OF CARBONYL COMPOUNDS, ESTERS, AND ALKOXYACETYLENES
WITH 2-DIPROPYLBORYLMETHYL-1,3-BUTADIENE AND THE SYNTHESIS
OF IPSENOL AND IPSDIENOL
Yu. N. Bubnov, M. Yu. Étinger, and A. V. Ignatenko
UDC 542.91:547.1'127

Allyl derivatives of boron are used extensively for obtaining, modifying, and functionalizing different classes of organic compounds [1]. In their properties, chemical activity, and uses, these compounds differ significantly from other organoboranes; this is due to their ability to react with allyl rearrangement [l]. The properties of allyl (I, $R=H$, methallyl ( $I, R=M e$ ), crotyl (II, $R=H$ ), and prenyl (II, $R=M e$ ) organoboranes [1, 2], as well as several 3-substituted organoboranes (III) (RX = RO, RS, $R_{3} S i$ ) [3], have been studied in detail.

The present communication presents the synthesis of the first representative of a new type of allylborane - 2-dipropylborylmethyl-1,3-butadiene (IV)-andits use in the isoprenylation of carbonyl compounds, esters, and alkoxyacetylenes.*

Reagent (IV) was obtained in a yield of $75-80 \%$ by the reaction of 2 -bromomethyl-1,3butadiene, alkoxydipropylborane, and aluminum activated with mercuric chloride in a small amount of ether.

## *For previous communication, see [4].

$$

$$
\mathrm{R}=\mathrm{C}_{6} \mathrm{H}_{13}, \mathrm{C}_{10} \mathrm{H}_{21} .
$$

Borane (IV) is stable in an inert gas atmosphere, is not polymerized, and can be stored for long periods of time; it is easily oxidized and hydrolyzed in air.

As might be expected, compound (IV) exhibits an enhanced chemical activity, which is characteristic for allyl derivatives of boron [1]. In the presence of water and alcohols, the bond between boron and the isoprenyl group is readily cleaved, affording isoprene and $\mathrm{Pr}_{2} \mathrm{BOR}$.

Borane (IV) reacts with aldehydes and ketones at -70 to $0^{\circ} \mathrm{C}$ by addition of the carbonyl group to form boron esters (V), whose reesterification with higher alcohols - for example, triethanolamine (TEA) - affords the corresponding dienyl alcohols (VIa-f) in a yield of $66-94 \%$.

$$
\begin{aligned}
& R=M e, R^{\prime}=H(a) ; R=P h, R^{\prime}=H(b), R=\alpha \text {-furyl, } \mathrm{B}^{\prime}=H(\mathrm{c}) ; R=\alpha \text {-thienyl } \\
& R^{\prime}=H(d) ; R=R^{\prime}=M e(e) ; R+R^{\prime}=\left(\mathrm{CH}_{2}\right)_{4}(f) ; R=\beta \text {-pyridyl, } R^{\prime}=H(g) .
\end{aligned}
$$

The reaction can be carried out without solvent by adding a carbonyl compound to (IV) in the ratio $1: 1$. If necessary, any inert solvent can be used: ether, THF, hexane, benzene, $\mathrm{CCl}_{4}$, etc.

We used the given isoprenylation method to synthesize ipsenol and ipsdienol [4], monoterpenyl alcohols that are the basic components of the aggregational sex pheromone of bark beetles (Ips and Pityokteines) [5]. ( $\pm$ )-Ipsenol (VII) was obtained in a yield of $94 \%$ by the reaction of compound (IV) with isovaleric aldehyde, and ( $\pm$ )-ipsdienol (VIII) was synthesized in a yield of $96 \%$ by the isoprenylation of 3,3-dimethylacrolein. *

In the synthesis of 3 -methylene-1-( $\beta$-pyridyl)pent-4-en-1-ol (VIg) from nicotinic aldehyde and compound (IV), 2 moles of (IV) per mole of carbonyl compound were used. The first mole of borane (IV) coordinates with the nitrogen atom of the pyridine ring to form a stable complex, which then undergoes isoprenylation by a second mole of (IV) to give the diboron compound.

When esters (IXa, b) react with compound (IV), they undergo diisoprenylation. However, these reactions are very slow. At room temperature and a (IV): (IX) ratio of $2: 1$, the reaction does not reach completion even after one week. When the reaction mixture was treated with TEA, tetraenyl (Xa) and pentaenyl (Xb) alcohols were obtained in a yield of over $60 \%$.

$$

The isoprenylation of esters takes place according to the following proposed scheme:

[^0]

The first step consists of addition across the $C=0$ bond, leading to the boron ketal (XI). This compound is unstable and decomposes ( $\beta$-elimination) to the dipropylboric acid ester and ketone (XII). The latter is more reactive than ester (IX) and reacts immediately with a second molecule of (IV), affording ester (XIII). A similar pattern was observed earlier in the allylborylation of esters by triallyl-, diallyl(alkyl)-, or allyl(dialkyl)boranes [7, 8]. It should be noted that allylborylation of carbonic acid esters, in contrast to the isoprenylation described in this work, is very rapid.

Compound (IV), like other allylboranes [1, 2], is readily added to ethoxyacetylene. The reaction takes place at -70 to $0^{\circ} \mathrm{C}$ and affords l-dipropylboryl-E-2-ethoxy-4-methylene1,5 -hexadiene (XIV) in a yield of $93 \%$.

This reaction is the first example of the isoprenylation of acetylene compounds.
When adduct (XIV) is treated with alcohols, the $B-C$ bond is readily cleaved to give 2 -ethoxy-4-methylene-1,5-hexadiene (XV). Compound (XV) can be conveniently obtained in a single flask without isolation of borane (XIV).

The hydrolysis of triene (XV) with $1 \%$ hydrochloric acid affords 2-vinyl-1-penten-4one (XVI). In contrast to carbinols (VIa-g), (VII), (VIII), and (Xa, b), triene (XV), ketone (XVI), and borane (XIV) are not hydrolyzed at $0-20^{\circ} \mathrm{C}$ and may be stored for a long time at this temperature in an inert gas atmosphere.

Thus, 2-dipropylborylmethyl-1,3-butadiene (IV) is a convenient C-5 syntone and may be used successfully to insert an isoprene fragment into different organic compounds.

Several reagents for inserting an isoprene fragment into organic compounds are known at present. Thus, the Lewis acid- or $\mathrm{Bu}_{4} \mathrm{NF}$-initiated isoprenylation of carbonyl compounds by means of 2-trimethylsilylmethyl-1,3-butadiene [9], its tin analogs [10], and isoprene (ene reaction) [11] have been described. The zinc analog of 2 -bromomethyl-1,3-butadiene has been shown to be a good isoprenylation reagent [12, 13] (attempts to obtain the analogous magnesium derivative and use it in synthesis have proven unsuccessful [12]).

It should be emphasized that the use of borane (IV) as an isoprenylation agent has many advantages compared with analogous derivatives, such as silicon and tin: the reactions take place under mild conditions, do not require catalysts, and are not complicated by side reactions. Moreover, borane (IV) can be used for the isoprenylation of acetylene compounds, which was not possible earlier. The structure of compounds (VI)-(XVI) was confirmed by IR and NMR spectroscopy.

The IR spectra of carbinols (VI), (VII), (VIII), and (X), boron esters (V), trienes (XIV) and (XV), and ketone (XVI) contain characteristic strong bands in the region 1595-1597 and $3090 \mathrm{~cm}^{-1}$; they contain bands of medium intensity at 1635 and $3010 \mathrm{~cm}^{-1}$. The spectra of alcohols (VI), (VII), (VII), and (X) have a broad band at $3300-3400 \mathrm{~cm}^{-1}$ (OH), with a shoulder at $3580 \mathrm{~cm}^{-1}$ (free hydroxyl). In the spectrum of borane (XIV) a very strong band at 1590 $\mathrm{cm}^{-1}(\mathrm{~B}-\mathrm{CH}=\mathrm{C})$ is superposed over the band at $1595 \mathrm{~cm}^{-1}$. Triene (XV) also has absorption bands at 1659 and $3120 \mathrm{~cm}^{-1}\left(\mathrm{CH}_{2}=\mathrm{C}^{\prime}\right)$, and ketone $(\mathrm{XIV})$ has a band at $1716 \mathrm{~cm}^{-1}(\mathrm{C}=0)$.

The structures of the synthesized compounds are also confirmed by ${ }^{1} H$ and ${ }^{13} \mathrm{C}$ NMR spectra. Diene system protons have chemical shifts at $6.20-6.50 \mathrm{ppm}$ for $>\mathrm{C}=\mathrm{CH}$ and at 4.50-
4.80 ppm for $\mathrm{CH}_{2}=\mathrm{C}$. The spin-spin interaction constants (SSIC) for protons in the trans position ( $J_{A X}$ trans) range from 16.80 to 18.40 Hz , and those for protons in the cis position ( $J_{\mathrm{BX}}{ }^{\text {cis }}$ ) range from 10.30 to 11.50 Hz , depending on the substituents.

The PMR spectra ( 250 MHz ) of carbinols (VIa-g), (VII), and (VIII) exhibit a geminal nonequivalence of the $\mathrm{CH}_{2}$ group at the asymmetric carbon atom at 0.05-0.15 ppm; the SSIC have the following values: Jgem $=14.00 \pm 0.20 \mathrm{~Hz}, \mathrm{Jvic}=8.60 \pm 0.20$ and $4.20-5.20 \mathrm{~Hz}$.

The chemical nonequivalence ( 0.01 ppm ) of the $\mathrm{CH}_{2}$ group in compound ( Xb ) is due to restrained rotation around the $\sigma$ bond. Among other characteristics of the PMR spectra, the small values of the geminal and allyl SSIC of the diene system protons are to be noted; these are smaller than the resolution of the instrument ( 0.02 Hz ) and do not appear in the spectra, which greatly simplifies their analysis. The very conservative nature of the chemical shifts and SSIC of the diene protons with respect to the effect of substituents should also be noted.

The ${ }^{13} \mathrm{C}$ spectra of the synthesized compounds contain all of the carbon atom signals. The isoprene fragment has signals at $42,114,119,139$, and 143 ppm .

## EXPERIMENTAL

All operations with organoboron compounds were carried out in a dry argon atmosphere.
IR spectra were recorded on a UR-20 instrument. PMR spectra were recorded on Bruker250 and Bruker-B-467 (60) instruments. ${ }^{11 B}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker AM-300 instrument. Chemical shifts are shown on the $\delta$ scale relative to TMS.

2-Bromomethyl-1,3-butadiene [bp $\left.63-65^{\circ} \mathrm{C}(82 \mathrm{~mm})\right]$ was synthesized from isoprene according to [14].

Dipropylboric Acid Decyl Ester. A $41.4-\mathrm{g}$ portion of decanol was added, after 40 min , to 36.6 g tripropylborane and 1 ml pivalic acid at $75-80^{\circ} \mathrm{C}$. The reaction proceeded with evolution of heat and was accompanied by the release of propane. The mixture was heated for 1 h at $75-80^{\circ} \mathrm{C} ; 46.6 \mathrm{~g}$ of product was isolated by distillation. Yield, 71\%; bp 109$112^{\circ} \mathrm{C}(1.5 \mathrm{~mm}) ; \mathrm{nd}^{20} 1.4330$. Found, \%: C $75.69 ; \mathrm{H} 13.82 ; \mathrm{B} 3.85 . \mathrm{C}_{16} \mathrm{H}_{35} \mathrm{BO}$. Calculated, \%: C 75.58; H 13.38; B 4.26.

Dipropylboric acid hexyl ester was obtained analogously from tripropylborane and hexanol in a yield of $79 \%$; bp $90-92^{\circ} \mathrm{C}$ ( 10 mm ) (cf. [15]).

2-Dipropylborylmethyl-1,3-butadiene (IV). A 7-g portion of aluminum shavings, 0.1 g mercuric chloride, and 40 ml ether were placed in a three-necked bottle equipped with a mixer, dropping funnel, and a reflux condenser. The mixture was stirred for 10 min to activate the aluminum, 3 ml of 2 -bromomethyl-I, 3 -butadiene were then added, and the mixture was heated to start the reaction (spontaneous boiling of ether). Then 28.0 g ( 0.19 mole ) of 2-bromomethyl-1,3-butadiene and 37.7 g ( 0.19 mole ) of dipropylboric acid hexyl ester were added dropwise. The reaction mass was boiled, with mixing, for another 2 h and cooled; ether was removed in a vacuum. The reaction mass was then heated carefully ( $70-110^{\circ} \mathrm{C}$ ) to distill the fraction with a bp of $30-60^{\circ} \mathrm{C}(1.5 \mathrm{~mm})$. A second distillation afforded 23.1 g (74\%) of borane (IV); bp $39-40^{\circ} \mathrm{C}(1.5 \mathrm{~mm}), \mathrm{n}_{\mathrm{D}}{ }^{20} 1.4569$. Found, \%: C 80.21 ; H 13.01; B 6.46. $\mathrm{C}_{11} \mathrm{H}_{21} \mathrm{~B}$. Calculated, \%: C 80.51 ; H 12.90; B 6.59. The PMR spectrum ( $250 \mathrm{MHz}, \mathrm{CDC1} \mathrm{~B}_{3}$ ) is shown in Table 1. IR spectrum (without solvent): $1590,1635,3090 \mathrm{~cm}^{-1}$.

Analogously, 8.0 g of aluminum, 0.1 g mercuric chloride, 20.5 g ( 0.14 mole) 2-bromo-methyl-1,3-butadiene, and 35.5 g ( 0.14 mole ) dipropylboric acid decyl ester afforded 18.0 g (79\%) of borane (IV).

Isoprenylation of Aldehydes. Synthesis of Ipsenol (VII). A 2.7-g portion of isovaleric aldehyde was added dropwise at $-30^{\circ} \mathrm{C}$ to 5.2 g of borane (IV) in a distillation apparatus. The mixture was kept at $20^{\circ} \mathrm{C}$ for 30 min , then 6 ml of triethanolamine (TEA) was added. After distillation, 4.5 g (94\%) of ipsenol (VII) was isolated; $\mathrm{bp} 94-96^{\circ} \mathrm{C}(19 \mathrm{~mm}), \mathrm{n}_{\mathrm{D}}{ }^{20} 1.4654$ (cf. [13]).

Carbinols (VIa), (VIe), (VIf), and ipsdienol (VIII) were obtained in an analogous manner (Table 2).

3-Methylene-1-phenyl-4-penten-1-ol (VIb). A $1.0-\mathrm{g}$ portion of benzaldehyde was added at $-70^{\circ} \mathrm{C}$ to 1.6 g of compound (IV) in 2 ml pentane. The mixture was kept for 30 min at $20^{\circ} \mathrm{C}$, pentane was distilled off in a vacuum, and 2.5 ml TEA was added. A $1.5-\mathrm{g}$ fraction ( $90 \%$ ) of

\%Found, \%: S 17.60. Calculated, \%: S 17.79.
**The material was purified on a column and was not distilled. *** Cf. [13].
****Found, \%: B4.71. Calculated, \%: B 4.62.
carbinol (VIb) was distilled from the reaction mixture; bp $98-104^{\circ} \mathrm{C}$ ( 3 mm ). This fraction was further purified on an $\mathrm{SiO}_{2}$ column ( $160 / 100 \mu$; eluent, hexane-ether, $7: 1$; $\mathrm{R}_{\mathrm{f}} 0.56$ (Silufol, pentane:ether $=5: 1$ ) and distilled; bp $76-77^{\circ} \mathrm{C}(2 \mathrm{~mm})$.

Alcohols (VIc, d) were synthesized in an analogous manner (see Table 2).
3-Methylene-( $\beta$-pyridyl)pent-4-en-l-ol (VIg). A l.0-g portion of 3-pyridine aldehyde in 1 ml benzene was added after 20 min to 1.5 g borane (IV) in 2 ml benzene at $0-5^{\circ} \mathrm{C}$. The mixture was colored bright yellow due to complex formation. An additional 1.5 g of compound (IV) was then added, and the mixture was kept for 1 h at $\sim 20^{\circ} \mathrm{C}$. The completion of the reaction was monitored by the disappearance of the band at $1735 \mathrm{~cm}^{-1}(\lambda \mathrm{C}=0)$ in the IR spectrum. Benzene was removed in a vacuum, the residue was dissolved in ether, and 4.0 ml of $\mathrm{H}_{2} \mathrm{O}$, 4.1 ml of 6 N NaOH , and 8.3 ml of $30 \% \mathrm{H}_{2} \mathrm{O}_{2}$ were added, with mixing ( -10 to $0^{\circ} \mathrm{C}$ ). The mixture was stirred for 3 h at $20^{\circ} \mathrm{C}$, the ether layer was removed, and the aqueous layer was extracted with ether ( $2 \times 10 \mathrm{ml}$ ). The extracts were cooled and dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After removal (in a vacuum) of ether and propanol, formed as a result of the oxidation of the $\operatorname{Pr}-\mathrm{B}$ 人 fragment, 1.9 g of a brownish oil was obtained. Chromatography on 60 g SiO (eluent, hexane: ether $=1: 6$ ) afforded 1 g ( $64 \%$ ) of carbinol ( VIg ); $\mathrm{n}_{\mathrm{D}}{ }^{20} 1.555, \mathrm{R}_{\mathrm{f}} 0.30$ (Silufol, hexane: ether = 1:3).

3,7-Dimethylene-5-methylnona-1,8-dien-5-ol (VIIIa). A 0.6-g portion of ethyl acetate was added at $0^{\circ} \mathrm{C}$ to 2.2 g of compound (IV). The mixture was kept for 1 week at $20^{\circ} \mathrm{C}$. Unreacted ethyl acetate was distilled in a vacuum, and 4.5 ml TEA was added to the residue. Pure carbinol (VIIIa) was isolated from the distilled fraction (bp $70-80^{\circ} \mathrm{C}$ at 2 mm ) by chromatography on $\mathrm{SiO}_{2} ; \mathrm{R}_{\mathrm{f}} 0.67$ (Silufol, pentane:ether $=5: 1$ ); bp $70-72^{\circ} \mathrm{C}(2 \mathrm{~mm})$; yield, 0.8 g (61\%) ; $n_{D}{ }^{20} 1.5084$.

3,7-Dimethylene-5-vinylnona-1,8-dien-5-ol (VIIIb) was obtained in an analogous manner; $R_{f} 0.50$ (Silufol, pentane:ether $=10: 1$ ) (see Table 2).

1-Dipropylboryl-E-2-ethoxy-4-methylene-1,5-hexadiene (XIV). A $0.9-\mathrm{g}$ portion of ethoxyacetylene was added at $-70^{\circ} \mathrm{C}$ to 2.2 g of borane (IV) in 5 ml pentane. The mixture was kept for 30 min at $\sim 20^{\circ} \mathrm{C}$, after which 2.4 g ( $93 \%$ ) of borane (XIV) was isolated by distillation; bp $75-78^{\circ} \mathrm{C}$ ( 1.5 mm ).

2-Ethoxy-4-methylene-1,5-hexadiene (XV). A 4.3-g portion of ethoxyacetylene was added at $-70^{\circ} \mathrm{C}$ to 10.0 g of borane (IV) in 5 ml pentane. The mixture was kept for 30 min at $\sim 20^{\circ} \mathrm{C}$. The solvent was then distilled in a vacuum, and 8 ml of TEA was added. Distillation afforded $8.2 \mathrm{~g}(98 \%)$ of triene (XV), with a bp of $50-58^{\circ} \mathrm{C}(19 \mathrm{~mm})$. Repeat distillation afforded $7.7 \mathrm{~g}(89 \%)$ of triene (XV), with a bp of $56-57^{\circ} \mathrm{C}$ ( 19 mm ).

2-Vinyl-1-penten-4-one (XVI). A mixture of 5.7 g of triene (XV) and 5 ml of $1 \%$ hydrochloric acid were mixed for 1.5 h at $\sim 20^{\circ} \mathrm{C}$. The organic layer was separated, and the aqueous layer was extracted with ether $(2 \times 5 \mathrm{ml})$. The extracts were pooled with the organic layer, washed with aqueous $\mathrm{K}_{2} \mathrm{CO}_{3}$ and water to a neutral reaction, and dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$. A $3.2-\mathrm{g}$ yield ( $71 \%$ ) of ketone (XVI) was obtained; bp $74-76^{\circ} \mathrm{C}$ ( 58 mm ); $\mathrm{nD}^{20} 1.4661$.

## CONCLUSIONS

1. 2-Dipropylborylmethyl-1,3-butadiene, the first example of allylboranes with a 1,3diene system, was synthesized by the reaction of 2-bromomethyl-1,3-butadiene, aluminum, and alkoxy(dipropyl)borane.
2. A convenient method was developed for obtaining dienyl and polyenyl alcohols, ketone, and vinyl esters. The method is based on the isoprenylation of carbonyl compounds, esters, and ethoxyacetylene by means of 2-dipropylborylmethyl-i,3-butadiene.
