### Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

**ABSTRACT**

The naturally-occurring indole alkaloid *des*-formylflustrabromine (dFBr; **1**) is one of the first agents shown to act as a selective positive allosteric modulator (PAM) at  $\alpha 4\beta 2$  nicotinic acetylcholine receptors (nAChRs). We previously deconstructed this agent to determine which of its structural features contribute to its actions and have identified an agent that might serve as the basis for a “*working pharmacophore*”. Here, we elaborate the dFBr (**1**;  $EC_{50} = 0.2 \mu M$ ) structure to identify how various structural modifications impact its actions. Electrophysiological studies with *Xenopus laevis* oocytes identified several compounds with dFBr-like potency and one, the 5-bromo analog of **1** (i.e., 5-bromo dFBr; **25**;  $EC_{50} = 0.4 \mu M$ ), with more than twice the efficacy of **1** as a PAM at  $\alpha 4\beta 2$  nAChRs.

**Keywords:** Positive allosteric modulator, electrophysiology, nAChRs,  $\alpha 4\beta 2$  PAM

## Introduction

The  $\alpha 4\beta 2$  subpopulation of nicotinic acetylcholine receptors (nAChRs) is implicated in drug and nicotine addiction, Parkinson's disease, depression, and pain.<sup>1-6</sup> However, there are very few, if any, agents that show substantial selectivity for this receptor subpopulation as agonists. Hence, there remains an unmet need for the development of  $\alpha 4\beta 2$  nAChR-selective agents. The natural product *des*-formylflustrabromine (dFBr; **1**) has been identified as one of the first positive allosteric modulators (PAMs) of  $\alpha 4\beta 2$  nAChRs with little to no action at other populations of nAChRs.<sup>7,8</sup> We “deconstructed” the dFBr (**1**) molecule in a stepwise manner to determine the contribution of its various structural features to  $\alpha 4\beta 2$  PAM action.<sup>9</sup> Found was that: *i*) conversion of the secondary amine of dFBr to a primary amine (i.e., **2**) reduced potency and efficacy, *ii*) reduction of the unsaturated side chain of dFBr (i.e., **4**) doubled its potency, with retention of efficacy, *iii*) debromination of **1** and **4** (i.e., **3** and **5**, respectively) reduced potency by at least one order of magnitude, but did not detract from ACh-potentiating action, and that *iv*) a branched indole 2-position substituent was favored.<sup>9</sup> Removal of the 2-position substituent, and even the simple removal of both *gem* dimethyl groups (i.e., of **1** and **4**), resulted in loss of ACh-potentiating action. Although compound **6** was substantially less potent than dFBr (**1**), it was the structurally simplest compound shown to potentiate the action of ACh at  $\alpha 4\beta 2$  nAChRs. In contrast, compound **7** failed to potentiate the actions of ACh.<sup>9</sup> Compound **6** would appear to represent the basis for a “*working pharmacophore*” and is the most abbreviated agent that retains dFBr-like PAM action.

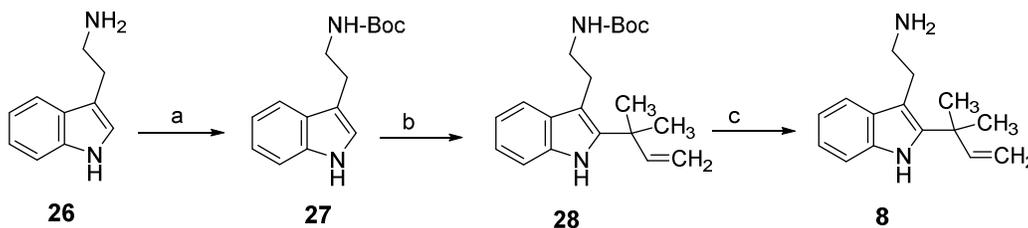

The above “*deconstruction*” investigation introduced no new substituents to the dFBr molecule; that is, dFBr substituents were simply “deleted” in a systematic fashion.<sup>9</sup> In the present study, we “*elaborated*” (for the most part) the structure of dFBr by adding new substituents or by modifying various structural aspects of dFBr. An initial goal was to confirm that a primary amine analog of dFBr (more specifically, of **3**; i.e., **8**) retains action in the absence of the 6-bromo group (and it might be noted that a decrease in potency was expected based on our earlier studies). But, the major goal of the study was to further explore the structure-activity relationships of dFBr to identify what structural features are required to retain or enhance its PAM actions on ACh at  $\alpha 4\beta 2$  nAChRs expressed in *Xenopus laevis* oocytes in an effort to identify those that might be ultimately exploited for the development of agents with enhanced potency and/or efficacy. At the time our work began, essentially nothing was known about the SAR of dFBr as an  $\alpha 4\beta 2$  nAChRs PAM other than what we have previously published.<sup>9</sup>

## Results

**Synthesis.** The compounds examined in this study were prepared as described below. For the purpose of this investigation, dFBr (**1**) was resynthesized as its hydrochloride salt as previously reported by us.<sup>8</sup> Compound **8**, the primary amine analog of **3**, was prepared in a similar manner (Scheme 1). That is, the primary amine of tryptamine (**26**) was protected by a Boc group (i.e., **27**), prenylated to **28** using prenyl 9-BBN,<sup>10</sup> and deprotected to afford **8**. This sequence also was used to prepare several other targets.

### Scheme 1. Synthesis of compound **8**.<sup>a</sup>

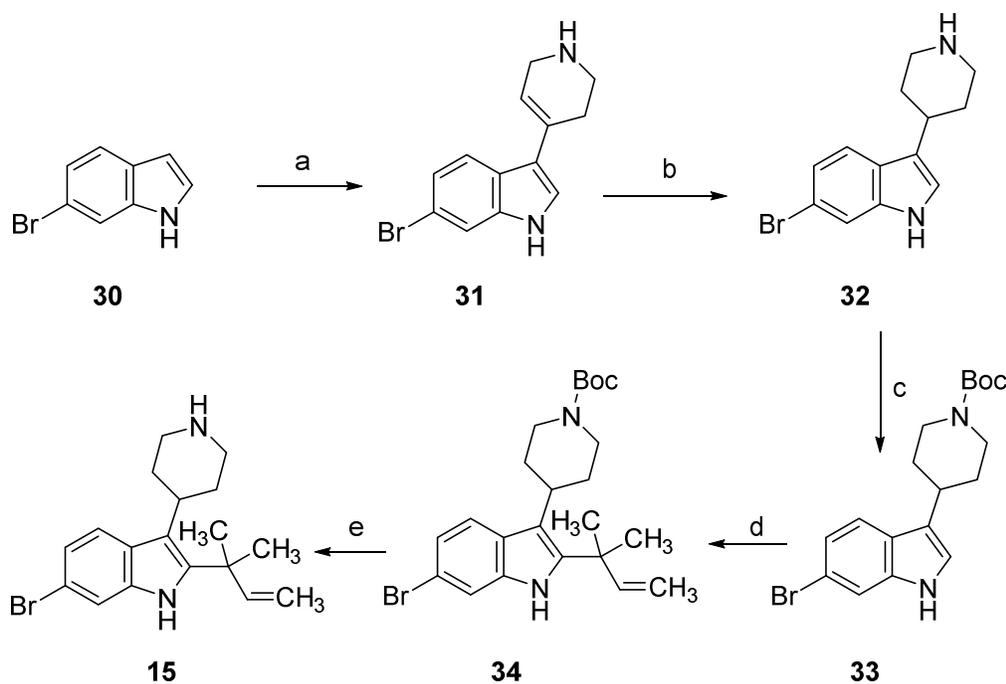

<sup>a</sup>Reagents: (a)  $\text{Boc}_2\text{O}$ ,  $\text{Et}_3\text{N}$ , DMF, room temperature, 20 h; (b) *t*-butyl hypochlorite, THF,  $-78\text{ }^\circ\text{C}$ , 45 min; prenyl 9-BBN, 3 h, room temperature; (c) HCl,  $\text{Et}_2\text{O}$ ,  $0\text{ }^\circ\text{C}$ .

The free base of dFBr (**1**) was reductively alkylated using formaldehyde and  $\text{NaCNBH}_3$  to tertiary amine **9**, which was subsequently methylated using MeI to give the N,N,N-trimethyl quaternary amine **10**. Alkylation of 5-bromo-2-(1,1-dimethylallyl)indole (**29**) with *N,N*-dimethylaminoethyl chloride furnished isotryptamine **11**. The free base of gramine **12** was prepared according to a literature procedure,<sup>11</sup> and converted to a water-soluble oxalate salt, and *N*-methylhomotryptamine (i.e., 3-(3-methylaminopropyl)-indole)<sup>12</sup> was Boc-protected, prenylated, and deprotected to afford **13** using the same

sequence of reactions shown in Scheme 1. Tetrahydro- $\beta$ -carboline **14** was obtained by cyclization of 6-bromotryptamine with acetone under Pictet-Spengler conditions.

Compound **15** was obtained as shown in Scheme 2. Condensation of 6-bromoindole (**30**) with 4-piperidone afforded tetrahydropyridine **31**; catalytic reduction of **31** to piperidine **32** followed by amine protection gave **33**. Prenylation (as described in Scheme 1) with subsequent de-protection provided **15**.

**Scheme 2.** Synthesis of compound **15**.<sup>a</sup>

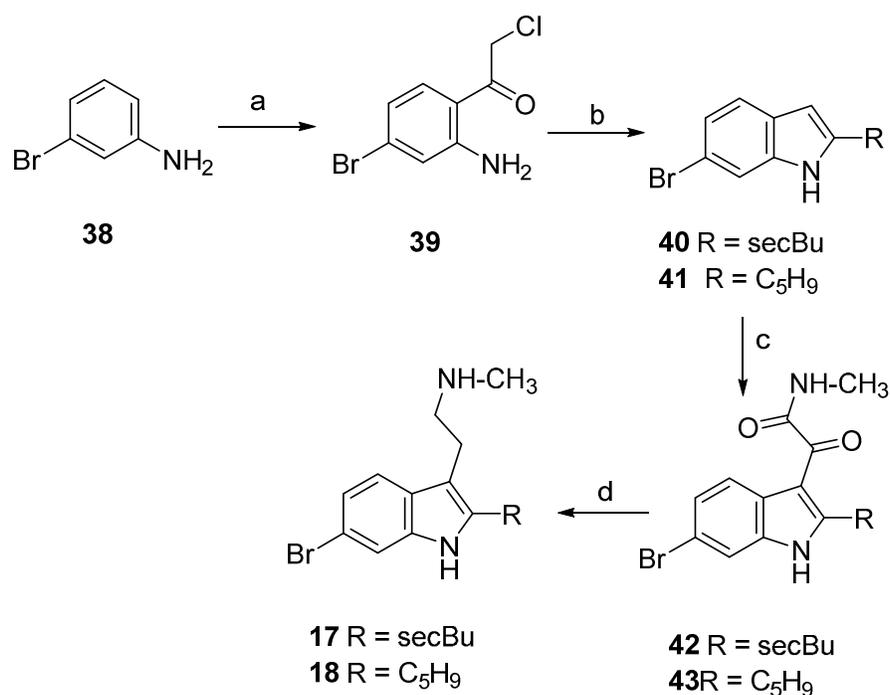

<sup>a</sup>Reagents: (a) 4-piperidone·HCl, KOH, CH<sub>3</sub>OH; (b) H<sub>2</sub>, PtO<sub>2</sub>, AcOH; (c) Boc<sub>2</sub>O, Et<sub>3</sub>N, CH<sub>2</sub>Cl<sub>2</sub>; (d) *i*-t-BuOCl, THF, *ii* prenyl 9-BBN, THF; (e) HCl, EtOAc.

Compound **16**, the  $\alpha$ -methyl analog of **2**, was prepared in the same manner shown in Scheme 1 using 1-(6-bromo-1*H*-indol-3-yl)propan-2-amine (**35**) as starting material; **35**

1  
2  
3 was obtained by catalytic reduction of 3-[2-nitroprop-1-en-1-yl]-6-bromoindole which had  
4  
5 been previously reported,<sup>13</sup> but not thoroughly characterized.  
6  
7  
8  
9

10 Compounds **17** and **18** were synthesized via a common route (Scheme 3). Acylation of  
11  
12 3-bromoaniline (**38**) with chloroacetyl chloride under Friedel-Crafts conditions afforded  
13  
14 **39**, which was subsequently cyclized by treatment with the appropriate Grignard  
15  
16 reagents to yield compounds **40** and **41**. The cyclization step involved a 1,2-aryl  
17  
18 migration as described by Pei et al.;<sup>14</sup> although the latter investigators synthesized a  
19  
20 variety of 2-substituted indoles, they never synthesized or utilized **39**. The remainder of  
21  
22 the syntheses involved a Speeter-Anthony<sup>15</sup> sequence where an indole is acylated with  
23  
24 oxalyl chloride, treated with an amine, and the resulting glyoxalyl amides reduced to the  
25  
26 corresponding amines.

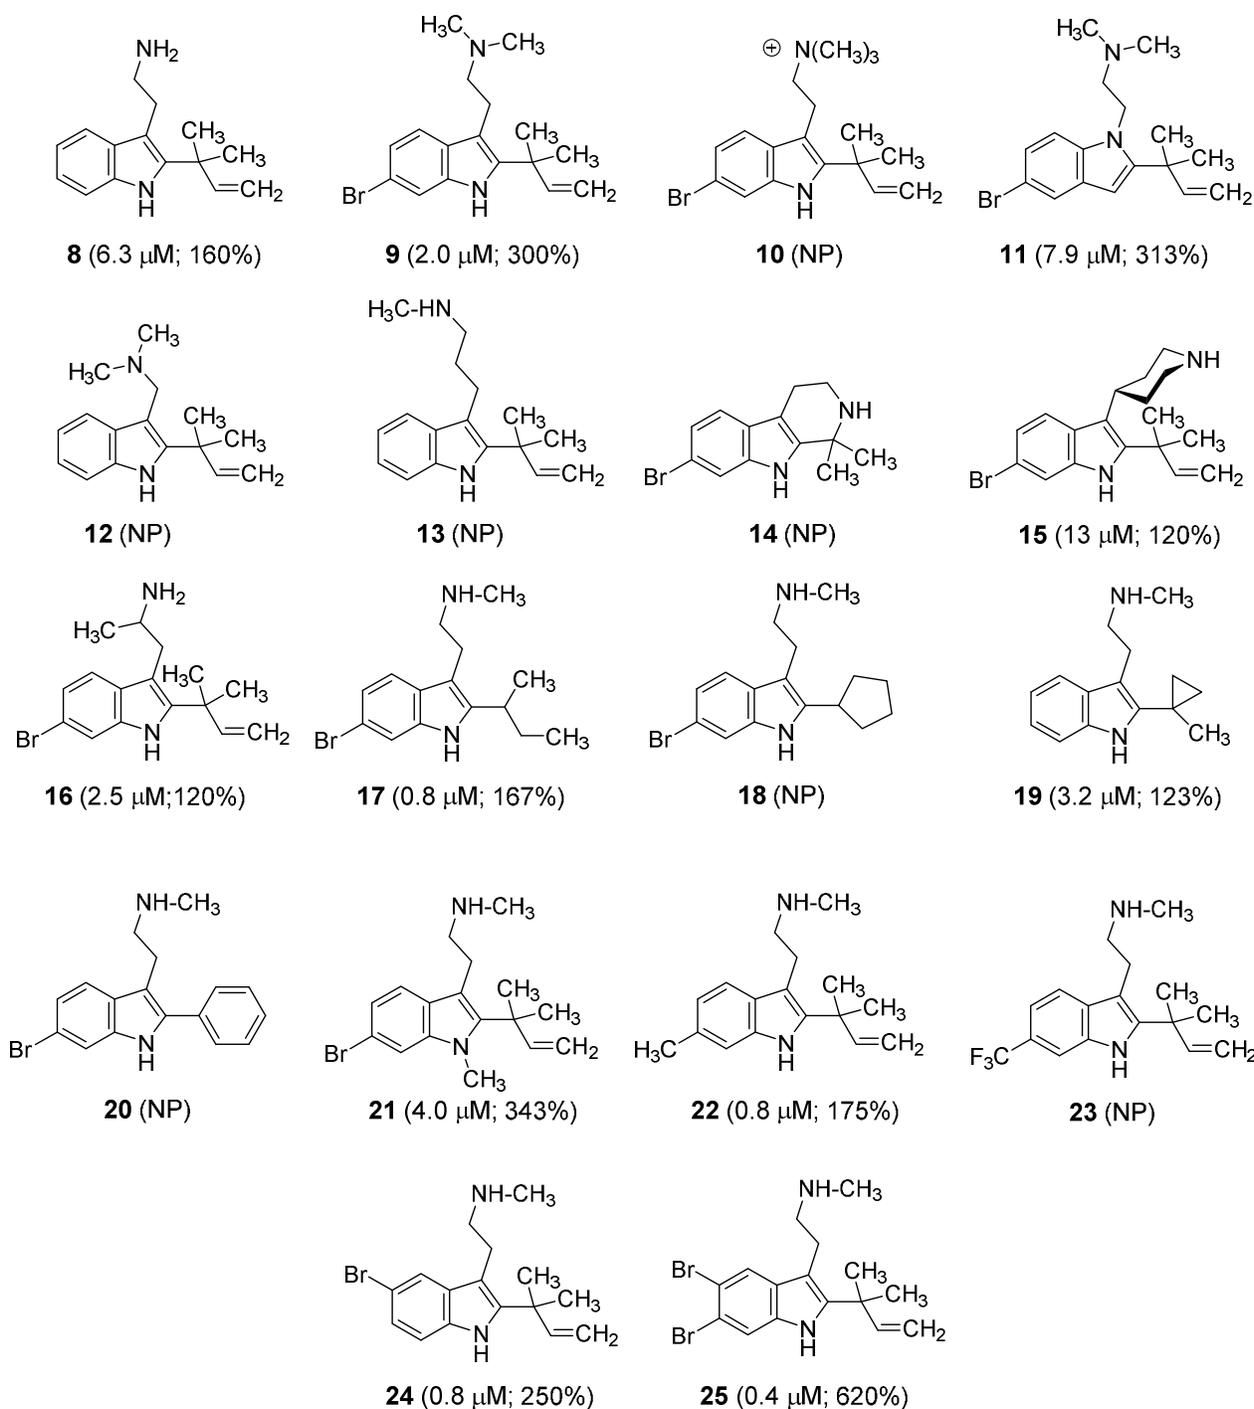

**Scheme 3.** Synthesis of **17** and **18**.<sup>a</sup>

<sup>a</sup>Reagents: (a) AlCl<sub>3</sub>, BCl<sub>3</sub>, ClCH<sub>2</sub>CN, DCM, reflux, overnight; (b) THF, rt, 1.5h; (c) *i* (COCl)<sub>2</sub>, Et<sub>2</sub>O, 0 °C, 1h, *ii* CH<sub>3</sub>NH<sub>2</sub> (40% in H<sub>2</sub>O), rt, overnight; (d) BH<sub>3</sub>·DMS, THF, reflux, overnight.

Compounds **19** and **20** were prepared from their corresponding 2-substituted indoles using a Speeter-Anthony sequence. Likewise, this reaction scheme was also used in the preparation of **22-25**; however, for the latter four compounds, 2-unsubstituted indoles were used as starting materials and once the desired *N*-methyltryptamines were obtained, the amine was Boc-protected prior to prenylation, followed by deprotection. *N*<sub>1</sub>-Methyl dFBr (**21**) was obtained by treatment of *N*-Boc-protected **1** with NaOH and MeI, followed by deprotection.

1  
2  
3 Electrophysiology. dFBr (**1**) was re-examined in *Xenopus* oocytes in the same manner  
4  
5 we described earlier,<sup>9</sup> and its potency ( $EC_{50} = 0.2 \mu\text{M}$ ) and efficacy (265%, relative to  
6  
7 ACh control: 100%) were consistent with what we have reported.<sup>8,9</sup> Data obtained for  
8  
9 the present compounds are detailed in Table 1, and “maximal effect” is defined as the  
10  
11  $I_{\text{max}}$  (calculated maximum current) for the potentiation dose-response curve. The  
12  
13 examined compounds also are shown in Figure 1 and their action and potency are  
14  
15 briefly summarized there for easy comparison (i.e., the figure provides their potency as  
16  
17  $EC_{50}$  values, and maximal potentiation, or it is indicated that they failed to potentiate the  
18  
19 actions of ACh – as noted by “NP” – no potentiation).

<sup>a</sup>EC<sub>50</sub>, I<sub>max</sub>, and IC<sub>50</sub> values were calculated using non linear regression to a bell-shaped dose response model. Hill slopes were fixed at 1 both for potentiation and inhibition. <sup>b</sup>I<sub>max</sub> values represent the percent change of the ACh I<sub>max</sub> after fitting the data to a bell-shaped dose response curve. <sup>c</sup>Maximal effect; no value is provided where there was no potentiation. <sup>d</sup>Maximum inhibition was set at 0 to enable estimation of IC<sub>50</sub> values and it was necessary to fit the data using the bell-shaped dose response equation. <sup>e</sup>NP: No potentiation.

1  
2  
3  
4  
5 We had previously shown that N-*des*-methyl dFBr (**2**) was nearly equipotent with dFBr  
6 (**1**).<sup>9</sup> Consistent with this finding, the primary amine counterpart of *des*-bromo dFBr (**8**;  
7  
8 EC<sub>50</sub> = 6.3 μM, Table 1) was nearly equipotent with its primary amine counterpart (i.e.,  
9  
10 *des*-bromo dFBr; **3**, EC<sub>50</sub> = 7.2 μM).<sup>9</sup> Nevertheless, **8** was substantially less potent than,  
11  
12 and only about half as efficacious as, **1**. The N,N-dimethyl tertiary amine analog of  
13  
14 dFBr, **9** (EC<sub>50</sub> = 2.0 μM), retained dFBr-like action, was at least equi-efficacious, but  
15  
16 was 10-fold less potent than dFBr (**1**) (Figure 2). In contrast, the N,N,N-trimethyl  
17  
18 quaternary amine analog of dFBr (i.e., **10**) failed to potentiate the actions of ACh and  
19  
20 only produced an inhibitory effect. The isotryptamine isostere of **9** (i.e., **11**; EC<sub>50</sub> = 7.9  
21  
22 μM) retained activity but was 4-fold less potent than **9**.

**Figure 2.** Typical responses and biphasic dose response curves for **1**, **9**, **15** and **24** showing potentiation and inhibition kinetics of analogs with different maximum observed responses. All potentiating compounds showed enhancement of ACh-induced responses at low concentrations followed by inhibition at higher concentrations. Inhibited responses typically displayed more rapid desensitization kinetics.

1  
2  
3 The side chain-shortened and side chain-elongated analogs **12** and **13** (Table 1),  
4 respectively, failed to potentiate the actions of ACh, as did the conformationally-  
5 constrained analog of **4** where the amine was tethered to the 2-position substituent in  
6 the form of a tetrahydro- $\beta$ -carboline (i.e., **14**). Piperidine **15** ( $EC_{50} = 13 \mu\text{M}$ ) was a very  
7 weak potentiating agent and only slightly (120%) enhanced the action of ACh.  
8  
9  
10 Compound **16** ( $EC_{50} = 2.5 \mu\text{M}$ ), the racemic  $\alpha$ -methyl analog of **2**, displayed  
11 substantially reduced potency and efficacy compared to dFBr.  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21

22 Compound **17** ( $EC_{50} = 0.8 \mu\text{M}$ ), the racemic mono *des*-methyl counterpart of **4**, retained  
23 dFBr-like action, but only half its efficacy; it might be noted that the individual optical  
24 isomers of **17** were not examined. Other 2-modified compounds were either less  
25 potent/efficacious (i.e., **19**) or inactive (i.e., **18**, **20**).  $N_1$ -Methyl dFBr (**21**;  $EC_{50} = 4.0 \mu\text{M}$ )  
26 was 20-fold less potent than dFBr (**1**) but retained its efficacy (Table 1). Replacement of  
27 the 6-bromo substituent of dFBr (**1**) by a methyl group (i.e., **22**) decreased potency by 4-  
28 fold and halved efficacy, whereas replacement with a trifluoromethyl group (i.e., **23**)  
29 resulted in no potentiation. Moving the bromo substituent to the 5-position (i.e., **24**)  
30 reduced potency by 4-fold but had relatively little effect on efficacy. 5-Bromo dFBr (i.e.,  
31 **25**), although only half as potent as **1**, displayed twice its efficacy.

## 10 Discussion

11  
12 We previously examined “*deconstructed*” analogs of dFBr (**1**) to understand which of  
13  
14 (and to what extent) its various structural attributes impact its action as a PAM at  $\alpha 4\beta 2$   
15  
16 ACh receptors.<sup>9</sup> A branched indole 2-position chain (although not chain unsaturation)  
17  
18 was a critical feature for activity, the simple 2-*n*-propyl counterpart of dFBr (i.e., dFBr  
19  
20 lacking both *gem*-dimethyl substituents) was inactive, but the 6-position bromo  
21  
22 substituent, although not required, was found important for efficacy.<sup>9</sup> Compound **6**,  
23  
24 although with 10-fold reduced potency, was demonstrated to be the minimal structure  
25  
26 retaining dFBr-like action. Here, we extend these structure-activity findings.  
27  
28  
29  
30  
31  
32

33 Confirming a prior finding (i.e., with **2**),<sup>9</sup> a primary amine (i.e., **8**) is tolerated for dFBr-like  
34  
35 action. Lacking a 6-bromo group, **8** was expected to be >10-fold less potent than **1**. This  
36  
37 was found to be the case. Table 1 shows that a tertiary amine, the simple N,N-  
38  
39 dimethylamine counterpart of **1**, also was tolerated, but that **9** was 10-fold less potent  
40  
41 than **1**; however, a quaternary amine counterpart of dFBr, **10**, was inactive. The latter  
42  
43 finding is compatible with the concept that dFBr-like compounds do not bind at the  $\alpha 4\beta 2$   
44  
45 receptor orthosteric site (i.e., ACh, which is a quaternary amine, binds at the orthosteric  
46  
47 site by definition). Whereas introduction of an  $\alpha$ -methyl group also was tolerated (i.e.,  
48  
49 **16**), other changes to the indole 3-position substituent (e.g. chain shortening, chain  
50  
51 extension, conformational restriction; i.e., **12-14**) resulted in loss of PAM action.  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5 A branched 2-position substituent was identified earlier as being important for activity.<sup>9</sup>  
6  
7 Here, it was found that removal of one of the methyl groups is tolerated (i.e., **17**); this  
8  
9 confirms the earlier suggestion that only one of the *gem* dimethyl groups might be  
10  
11 required,<sup>9</sup> and this might be related to the lipophilicity of the substituent. Nevertheless,  
12  
13 **17** displayed only half the ACh potentiating effect of dFBr. Compound **6** showed  
14  
15 potentiating action whereas its 2-isopropyl counterpart, **7**, was inactive.<sup>9</sup> Likewise,  
16  
17 “extending” the isopropyl group to a bulkier cyclopentyl group (i.e., **18**) resulted in loss  
18  
19 of action. At this time, given the results with **17**, we cannot explain this finding. However,  
20  
21 like **6**, the cyclopropyl analog **19** was active but only weakly potentiated the action of  
22  
23 ACh (i.e., to 123%). The 2-phenyl counterpart of dFBr (i.e., **20**), which also might be  
24  
25 considered a “branched” substituent, was found to be inactive.  
26  
27  
28  
29  
30  
31  
32

33 Because none of the above structural alterations resulted in enhanced potency or  
34  
35 efficacy, attention was directed to the indole nucleus; the 2- and 3-position substituents  
36  
37 of dFBr (**1**) were retained. Compound **11**, the isotryptamine counterpart of **9**, was about  
38  
39 40-fold less potent than than **1**, and 4-fold less potent than **9**, suggesting that the  
40  
41 location or presence of the indolic N or NH substituent plays a role in PAM potency.  
42  
43 Interestingly, the N<sub>1</sub>-methyl counterpart of dFBr (i.e., **21**) displayed 20-fold reduced  
44  
45 potency relative to dFBr suggesting that the indolic 1-position hydrogen atom might be  
46  
47 involved in the potency of these compounds.

1  
2  
3 Because removal of the 6-bromo group of dFBr decreased its potency by at least 10-  
4 fold (reference 9 and the present study), an attempt was made to determine if this was  
5 related to the lipophilic or electronic character of the bromo substituent. Because the  
6 bromo group of dFBr (**1**) and the methyl group of **22** are electronically opposite, and  
7 because a bromo group is more lipophilic than a methyl group ( $\pi = 0.86$  and  $0.56$ ,  
8 respectively<sup>16</sup>), it would seem that its contribution might be related to lipophilicity. The  
9 trifluoromethyl group of inactive **23** is equi-lipophilic ( $\pi = 0.88$ ) with a bromo group;  
10 however, it is sterically larger than a bromo or methyl group<sup>17,18</sup> and might not be  
11 accommodated by the binding pocket. Indeed, several “size” indicies were examined  
12 and are consistent with this concept (see Table S1, Supporting Information).

27  
28

29 Translocation of the 6-bromo group to the 5-position resulted in a compound (i.e., **24**)  
30 that was slightly less potent but equi-efficacious with dFBr. Thus, the position of the 6-  
31 bromo group, although perhaps optimal, would not appear to be critical for ACh-  
32 enhancing PAM action. The 5,6-dibromo indolic compound **25** was only slightly less  
33 potent than dFBr, but displayed twice its efficacy (620%). Additional 5-substituted and  
34 5,6-disubstituted compounds remain to be examined.  
35  
36  
37

40  
41  
42  
43  
44

45 Over the last few years attempts have been made, using site-directed mutagenesis, to  
46 localize sites on  $\alpha 4\beta 2$  receptors where dFBr might act to elicit its allosteric effects;  
47 several potential sites have been identified.<sup>19-21</sup> In particular, Deba et al.<sup>21</sup> have  
48 proposed two distinct sites and, additionally, have modeled possible dFBr interactions.  
49  
50  
51  
52  
53  
54 In one site, the protonated amine is proposed to form a hydrogen bond with the  
55  
56  
57  
58  
59  
60

1  
2  
3 carbonyl oxygen atom of a valine (V609) residue, and the 2-position alkyl group is  
4 involved in hydrophobic interactions with lysine (L317) and phenylalanine (F312)  
5 residues. This is consistent with our findings that the quaternary amine **10** is inactive,  
6 and that a 2-position (branched) alkyl substituent contributes to activity.<sup>9</sup> Furthermore,  
7 the enhanced potency of **4** over dFBr might be related to the greater lipophilicity of the  
8 ethyl group relative to its ethylene counterpart ( $\pi = 1.02$  and  $0.82$  for  $\text{CH}_2\text{CH}_3$  and  
9  $\text{CH}=\text{CH}_2$ , respectively<sup>16</sup>). Docked in this site, the 6-bromo group of dFBr is within 3 Å of  
10 a phenylalanine (F316) residue, implicating a possible hydrophobic interaction. This is  
11 also in accord with the action of **22**. The second binding site involves, in addition to  
12 hydrophobic interactions between the (branched) 2-position alkyl group and a leucine  
13 moiety (L256), a hydrogen bond between the indole NH of dFBr and a cysteine (C259)  
14 residue.<sup>21</sup> The latter is consistent with the reduced potency of **21** (although it might be  
15 noted that **21** retained dFBr-like efficacy as a potentiating agent). Future homology  
16 modelling/docking studies can be specifically informed by results such as those  
17 provided here to validate and/or refine future models.

35  
36  
37  
38  
39

40 Thus far, the naturally-occurring **1** seems to be a nearly optimal structure (i.e., with  
41 regard to potency *and* efficacy) for dFBr-like compounds to potentiate the actions of  
42 ACh at  $\alpha 4\beta 2$  nAChRs. But, it might be noted that potency and efficacy do not co-vary.  
43 Apart from the saturated dFBr analog **4**, which was about twice as potent as, but equi-  
44 efficacious with, dFBr (**1**),<sup>9</sup> none of the compounds examined here displayed  
45 substantially enhanced potency *and* efficacy. Potential structural modifications of **1**  
46 resulting in retention of potency and efficacy, thus far, appear limited. It is evident that

1  
2  
3 manipulation of substituents on the indole nucleus (apart from the 2- and 3-positions)  
4  
5 can favorably impact activity and result in compounds with sub-micromolar potency and  
6  
7 even, as with **25**, enhanced efficacy. Future studies will focus primarily on the indole  
8  
9 ring and substituents at the indole 4- – 7-positions. The ideal goal would be an agent  
10  
11 that enhances the actions of ACh without acting as an antagonist of ACh at higher  
12  
13 concentrations. This goal has yet to be achieved. But, the present findings provide  
14  
15 insight as to how dFBr substituents impact the action of ACh, provide the most complete  
16  
17 SAR study of dFBr (**1**) to date, and can inform future modeling/docking studies.

## Experimental

### Synthesis

Melting points (mp) were measured on a Thomas-Hoover melting point apparatus using glass capillary tubes and are uncorrected. <sup>1</sup>H NMR spectra were recorded on a Varian 400 MHz spectrometer using tetramethylsilane (TMS) as an internal standard; peak positions are given in parts per million (δ). UHPLC-MS were recorded on a Perkin Elmer Flexar UHPLC with AxION 2 Time of Flight (TOF) mass spectrometer and the molecular weight of the compounds was within 0.05% of calculated values. Elemental analysis was performed on all target compounds by Atlantic Microlab Inc. (Norcross, GA) for the elements indicated and the results were typically within 0.4% of calculated values.

Infrared spectra were obtained on a Thermo Nicolet iS10 FT-IR. Flash chromatography was performed on a CombiFlash Companion/TS instrument (Telodyne Isco Inc., Lincoln, NE) using packed silica gel (Silica Gel 230-400 mesh) columns (RediSep Rf Normal-phase Silica Flash Column, Teledyne Isco Inc., Lincoln, NE). All reactions were monitored by thin-layer chromatography (TLC) on silica gel GHLF plates (250 μ, 2.5 x 10 cm; Analtech Inc., Newark, DE).

**2-(1,1-Dimethylallyl)tryptamine Hydrochloride (8).** Gaseous HCl was bubbled into a solution of *tert*-butyl-2-(2-(1,1-dimethylallyl)-1*H*-indol-3-yl)ethylcarbamate **28** (0.4 g) in anhydrous Et<sub>2</sub>O (20 mL) at 0 °C. The reaction mixture was allowed to stir for 24 h and the solvent was evaporated to yield a purple solid which was recrystallized from *i*-PrOH/Et<sub>2</sub>O to yield 0.1 g (28%) of **8** as brown crystals: mp 231-232 °C; <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>) δ 1.50 (s, 6H, CH<sub>3</sub>), 2.86 (t, 2H, CH<sub>2</sub>), 3.07 (t, 2H, CH<sub>2</sub>), 5.06-5.11 (m, 2H,

1  
2  
3 CH<sub>2</sub>), 6.12-6.18 (m, 1H, CH), 6.95-7.06 (m, 2H, Ar), 7.34 (d, *J* = 7.9 Hz, 1H, Ar), 7.51 (d,  
4  
5 *J* = 7.8 Hz, 1H, Ar), 8.05 (br s, 3H, NH<sub>3</sub><sup>+</sup> aliphatic), 10.59 (br s, 1H, indolic NH). Anal.

8  
9  
10  
11  
12 **6-Bromo-2-(1,1-dimethylallyl)-*N,N*-dimethyltryptamine Oxalate (9)**. Formaldehyde  
13  
14 (0.09 mL, 1.25 mmol) and NaBH<sub>3</sub>CN (0.03 g, 0.5 mmol) were added to a stirred solution  
15  
16 of **1** (free base, 0.08 g, 0.25 mmol) in CH<sub>3</sub>CN (15 mL) under a N<sub>2</sub> atmosphere. The  
17  
18 reaction mixture was allowed to stir for 1 h at room temperature, and then 2N HCl (8  
19  
20 mL) was added in a dropwise manner. After stirring for 2 h, the reaction mixture was  
21  
22 diluted with Et<sub>2</sub>O (10 mL), and the organic layer was separated and washed with H<sub>2</sub>O (2  
23  
24 x 10 mL). The aqueous portions were combined, basified by addition of NaHCO<sub>3</sub> (pH  
25  
26 8), and extracted with CH<sub>2</sub>Cl<sub>2</sub> (3 x 10 mL). The organic portions were combined, dried  
27  
28 (Na<sub>2</sub>SO<sub>4</sub>), and concentrated under reduced pressure. The residue was purified by  
29  
30 column chromatography (Aldrich silica gel 60) using DCM/MeOH (10:1) as eluent to  
31  
32 afford the free base of **9** (0.06 g, 60% yield) as an oil: <sup>1</sup>H NMR (CDCl<sub>3</sub>): δ 1.53 (s, 6H,  
33  
34 2 x CH<sub>3</sub>), 2.34 (s, 6 H, 2 x CH<sub>3</sub>), 2.48-2.52(m, 2H, CH<sub>2</sub>), 2.96-3.00 (m, 2H, CH<sub>2</sub>), 5.14-  
35  
36 5.18 (m, 2H, CH<sub>2</sub>), 6.07-6.14 (m, 1H, CH), 7.15 (d, *J* = 1.6 Hz, 1H, Ar-H), 7.36 (d, *J* =  
37  
38 1.6, 1H, Ar-H), 7.42 (s, 1H, 2 x Ar-H), 7.83 (b s, 1H, NH). A solution of the free base  
39  
40 (0.05 g, 0.15 mmol) and oxalic acid (0.01 g, 0.15 mmol) in CHCl<sub>3</sub> (3 mL) was allowed to  
41  
42 stir for 0.5 h and the precipitate was collected by filtration. The solid product was  
43  
44 recrystallized from *i*-PrOH to afford **9** (0.02 g, 36% yield) as a white solid: mp 172-173  
45  
46 °C; <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>) δ 1.58 (s, 6H, 2 x CH<sub>3</sub>), 2.73 (s, 6H, 2 x N-CH<sub>3</sub>), 4.39 (br.s, 2H,  
47  
48 CH<sub>2</sub>), 5.25-5.29 (m, 2H, CH<sub>2</sub>), 6.31-6.38 (m, 1H, CH), 7.25 (d, *J* = 8.44 Hz, 1H, ArH),

3 **2-(1,1-Dimethylallyl)gramine Hydrogen Oxalate (12)**. Dimethylamine (40%, 0.1 mL,  
4 0.8 mmol) and HCHO (37%, 0.7 mL, 0.8 mmol) were added to a solution of 2-(1,1-  
5 dimethylallyl)-1*H*-indole<sup>11</sup> (0.10 g, 0.5 mmol) in glacial HOAc (3 mL) maintained at 5 °C.  
6  
7 When the vapors ceased, MeOH (4 mL) was added to make a clear solution and the  
8 reaction mixture was allowed to stir overnight at room temperature. The organic solvent  
9  
10 was removed by evaporation under reduced pressure and the solution was basified with  
11 NaOH (3M, to pH 10). The aqueous portion was extracted with Et<sub>2</sub>O (3 x 30 mL) and  
12  
13 the combined organic portion was washed with H<sub>2</sub>O (3 x 50 mL), brine (50 mL), dried  
14  
15 (Na<sub>2</sub>SO<sub>4</sub>), and the solvent was removed under reduced pressure to yield the gramine as  
16  
17 a free base which was converted to an oxalate salt by addition of a saturated oxalic acid  
18  
19 solution in anhydrous Et<sub>2</sub>O (5 mL) to a solution of crude 2-(1,1-dimethylallyl)gramine in  
20  
21 anhydrous Et<sub>2</sub>O (5 mL) at 0 °C. The precipitate was collected by filtration, dried and  
22  
23 recrystallized from *i*-PrOH to afford 0.04 g (22%) of **12** as white crystals: mp 155-158  
24

CH<sub>2</sub>), 6.12-6.19 (m, 1H, CH), 7.71 (s, 1H, Ar), 8.03 (s, 1H, Ar), 8.81 (br s, 1H, NH<sup>+</sup> aliphatic), 10.98 (s, 1H, indolic NH). Anal. Calcd for (C<sub>16</sub>H<sub>20</sub>Br<sub>2</sub>N<sub>2</sub>·HCl) C, H, N.

***tert*-Butyl-2-(2-(1,1-dimethylallyl)-1*H*-indol-3-yl)ethylcarbamate (28).**

*tert*-Butyl hypochlorite (0.5 g, 4.6 mmol) was added to a solution of *tert*-butyl-2-(1*H*-indol-3-yl)ethylcarbamate **27**<sup>27</sup> (1.0 g, 3.8 mmol) and Et<sub>3</sub>N (0.5 g, 4.6 mmol) in anhydrous THF (25 mL) at -78 °C and the solution was allowed to stir for 45 min. Freshly prepared prenyl 9-BBN<sup>10</sup> (7.7 mmol) was added in a dropwise manner over 15 min while maintaining the temperature at -55 °C. The reaction mixture was allowed to warm to room temperature and was stirred for an additional 3 h. Sodium hydroxide (3M, 10 mL) and H<sub>2</sub>O<sub>2</sub> (30% v/v, 10 mL) were added in a dropwise manner and the reaction mixture was allowed to stir for 1 h at room temperature. The reaction was diluted with Et<sub>2</sub>O (100 mL), the organic layer was separated and washed with H<sub>2</sub>O (3 x 60 mL), brine (80 mL) and dried (Na<sub>2</sub>SO<sub>4</sub>). The solvent was evaporated under reduced pressure to yield a crude residue which was purified by column chromatography (silica gel; hexanes/EtOAc; 100:1 to 5:1) to afford 0.5 g (36%) of **28** as a white foam: <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ 1.37 (s, 9H, CH<sub>3</sub>), 1.47 (s, 6H, CH<sub>3</sub>), 2.96 (t, 2H, CH<sub>2</sub>), 3.32 (m, 2H, CH<sub>2</sub>), 4.53 (br s, 1H, NH aliphatic), 5.06-5.11 (m, 2H, CH<sub>2</sub>), 6.01-6.08 (m, 1H, CH), 6.98-7.08 (m, 2H, Ar), 7.21 (d, *J* = 8.0 Hz, 1H, Ar), 7.48 (d, *J* = 7.8 Hz, 1H, Ar), 7.79 (br s, 1H, indolic NH). Compound **28** was used in the preparation of **8**.

**6-Bromo-3-(1,2,3,6-tetrahydropyridin-4-yl)-1*H*-indole (31).** 4-Piperidone

hydrochloride monohydrate (1.96 g, 12.75 mmol) was added in one portion to a solution

1  
2  
3 of 6-bromoindole (**30**) (1.0 g, 5.1 mmol) and KOH (1.5 g, 27.03 mmol) in methanol (25  
4 mL) and the mixture was heated at reflux for 5 h. After cooling the reaction mixture, the  
5 potassium chloride precipitate was removed by filtration and the solution volume was  
6 reduced to 1/3 under reduced pressure. Addition of water (5 mL) was followed by  
7 filtration of the precipitate. After washing with dichloromethane **31** was obtained as  
8 yellow solid (1.20 g, 85%): mp 143-145 °C; <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>) δ 2.43 (m, 2H, CH<sub>2</sub>),  
9 2.99-3.02 (t, *J* = 5.7 Hz, 2H, CH<sub>2</sub>), 3.46-3.48 (m, 2H, CH<sub>2</sub>), 6.20 (m, 1H, CH), 7.18-7.21  
10 (dd, *J* = 1.8 Hz, *J* = 8.5 Hz, 1H, Ar-H), 7.46 (d, *J* = 2.1 Hz, 1H, Ar-H), 7.61 (d, *J* = 1.8  
11 Hz, 1H, Ar-H), 7.82 (d, *J* = 8.5 Hz, 1H, CH), 11.29 (s, 1H, NH).

### 35 Electrophysiology.

36  
37 Two electrode voltage clamp (TEVC) electrophysiology was used to evaluate dFBr and  
38  
39 dFBr analogs. cDNA for α4 and β2 receptors was synthesized by GeneArt Inc.  
40  
41 (Burlingame, CA) from sequences obtained from the National Center for Biotechnology  
42  
43 Information (sequences NM\_000744.5 and NM\_000748.2 respectively) and inserted  
44  
45 into a pcDNA3.1 expression vector. High yield capped mRNA transcripts were obtained  
46  
47 using the mMessage mMachine transcription kit (Ambion, Austin, TX) and injected by  
48  
49 microinjection into collagenase treated *Xenopus* oocytes using a ratio of α4 to β2 of 1:1.  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Current recordings were made using an automated TEVC recording system  
4  
5 incorporating a Gilson auto sampler injection system and a Warner Instruments OC-  
6  
7 725C oocyte voltage clamp amplifier as previously described.<sup>30</sup> Data collection was  
8  
9 performed using Axon instruments pClamp software.  
10  
11  
12

13  
14 Current and Voltage electrodes (1-4 M $\Omega$ ) were filled with a 3M KCl solution. Oocytes  
15  
16 were held in a vertical flow chamber of 200  $\mu$ l volume and clamped at a holding  
17  
18 potential of -60 mV. Oocytes were continuously perfused with a modified ND-96 buffer  
19  
20 incorporating phosphate rather than HEPES buffer due to the previous finding that  
21  
22 HEPES modulates the high sensitivity isoform of the  $\alpha$ 4 $\beta$ 2 receptor (96 mM NaCl, 2 mM  
23  
24 KCl, 1.8 mM CaCl<sub>2</sub>, 1 mM MgCl<sub>2</sub>, and 2 mM phosphate, pH 7.4).<sup>31</sup> Test compounds  
25  
26 were dissolved in identical Phosphate-ND-96 buffer and injected into the chamber at a  
27  
28 rate of 20 ml/min using the auto sampler injection system.  
29  
30  
31  
32  
33

34  
35 Oocytes were first exposed to increasing concentrations of each analog alone to  
36  
37 determine if any were capable of activating receptors. Since no analogs elicited  
38  
39 responses when applied alone, oocytes were co-perfused for a duration of 10 s with  
40  
41 each dFBr analog and 100  $\mu$ M ACh to identify inhibition or potentiation of ACh-induced  
42  
43 responses. Responses for dFBr analogs were evaluated at concentrations ranging from  
44  
45 0.01 $\mu$ M to 300  $\mu$ M and the peak amplitudes used to create dose response curves. In  
46  
47 order to permit comparison of responses from different oocytes, individual responses to  
48  
49 drug application were normalized to control responses elicited using 100  $\mu$ M ACh in the  
50  
51 absence of dFBr or its analogs. Oocytes were washed with HEPES-ND96 for 7 min  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 prior to reapplication of another drug concentration. Oocytes were periodically exposed  
4  
5 to 100  $\mu\text{M}$  ACh to assure responses returned to normal following washout of the  
6  
7 analog/ACh combination. All data were collected from at least four replicate  
8  
9 experiments using four oocytes obtained from at least two different frogs.  
10  
11

12  
13  
14 Currents were recorded by either application of ACh alone or by co-application of test  
15  
16 compounds with a fixed 100  $\mu\text{M}$  concentration of ACh. To compare responses from  
17  
18 different oocytes, individual responses to drug application were normalized to the  
19  
20 control responses elicited by 100  $\mu\text{M}$  ACh. Data were collected from at least four  
21  
22 replicate experiments using oocytes obtained from at least two different frogs.  
23  
24  
25

26  
27  
28  $\text{EC}_{50}$ ,  $I_{\text{max}}$  and  $\text{IC}_{50}$  values were determined from normalized, pooled data.  
29  
30

31  
32  
33 Concentration-response profiles were determined using nonlinear curve fitting and  
34  
35 GraphPad Prism software (GraphPad Software, La Jolla, CA) using standard built-in  
36  
37 algorithms. All analogs that potentiated ACh-induced responses showed biphasic (bell  
38  
39 shaped) dose response curves.  $\text{EC}_{50}$  and (where possible)  $\text{IC}_{50}$  values were determined  
40  
41 for these curves using a biphasic dose response equation that simultaneously fit both  
42  
43 the potentiation and inhibition curves and enabled determination of the  $I_{\text{max}}$  for  
44  
45 potentiation.<sup>31</sup> The percent change in  $I_{\text{max}}$  calculated using this equation (Table 1)  
46  
47 represents the calculated change in  $I_{\text{max}}$  due to the addition of the potentiator. A  
48  
49 maximum observed effect was also determined from the peak of the dose response  
50  
51 curve. Typically the maximum effect is substantially less than the  $I_{\text{max}}$  change due to the  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 contribution of the inhibition phase of the curve. Dose-response curves where the  
4  
5  $IC_{50}/EC_{50}$  ratio was less than 10 were particularly challenging to fit using the biphasic  
6  
7 equation and thus required constraint of some variables. For consistency, the initial  
8  
9 plateau for all fits was typically fixed at 1 (i.e., dFBr alone) and the Hill slopes were  
10  
11 constrained to 1 for both the potentiation and inhibition phases. Some curves required  
12  
13 an additional constraint of plateau 2 (maximum inhibition) to be constrained to 0 in order  
14  
15 to determine an  $IC_{50}$  value as indicated in Table 1. For compounds that showed only  
16  
17 inhibition of ACh-induced responses,  $IC_{50}$  values were determined using a standard  
18  
19 inhibition dose-response equation.

## SUPPORTING INFORMATION

Physicochemical properties of 6-position substituents and the total volume of selected compounds.

## AUTHOR INFORMATION

### Corresponding Author

E-mail: [glennon@vcu.edu](mailto:glennon@vcu.edu)

Mailing Address: Department of Medicinal Chemistry, School of Pharmacy, Virginia Commonwealth University, Richmond, VA 23298, USA.

**ORCID** Richard A. Glennon 0000-0002-3600-9045

### Author Contributions

The project was proposed by RAG and MKS. NG, AJ, and RF-P conducted the synthesis under the direct supervision of MD. YH and YM conducted the electrophysiological studies under the direct supervision of MKS. MD and RAG prepared the first draft of the manuscript. All co-authors had an opportunity to contribute and make necessary corrections to the manuscript prior to submission.

### Funding

This work was supported, in part, by the National Institutes of Health, National Institute of Neurological Disorders and Stroke [R01 NS066059]. NG was partially supported by TA grant DA 007027.
