ABSTRACT: The first Suzuki cross-couplings of unactivated tertiary alkyl electrophiles are described. The method employs a readily accessible catalyst (NiBr$_2$·diglyme/4,4′-di-*tert*-butyl-2,2′-bipyridine, both commercially available) and represents the initial example of the use of a group 10 catalyst to cross-couple unactivated tertiary electrophiles to form C–C bonds. This approach to the synthesis of all-carbon quaternary carbon centers does not suffer from isomerization of the alkyl group, in contrast with the umpolung strategy for this bond construction (cross-coupling of a tertiary alkylmetal with an aryl electrophile). Preliminary mechanistic studies are consistent with the generation of a radical intermediate along the reaction pathway.

During the past decade, substantial progress has been accomplished in the development of metal-catalyzed cross-coupling reactions of alkyl electrophiles with organometallic reagents to form C–C bonds.[1,2] Nearly all reports have focused on couplings of primary and secondary electrophiles; in contrast, there have been only isolated examples of successful reactions with unactivated tertiary electrophiles. In particular, Oshima has described cross-couplings with indenyllithium (Ag catalyst), cyclopentadienylmagnesium (Cu), benzylmagnesium (Ag), allylmagnesium (Co, Cu, and Ag), and allyl- and benzylzinc (Ag) reagents.[3]

The difficulty in coupling tertiary alkyl electrophiles can be attributed to a variety of factors, including a low propensity to undergo oxidative addition via an S$_N$2 or a direct-insertion pathway. We and others have demonstrated that, for an array of Ni-catalyzed cross-coupling reactions of unactivated primary and secondary alkyl halides, oxidative addition likely proceeds through an inner-sphere electron-transfer pathway.[4–6] In view of the relative stability of tertiary radicals, this mechanism could be conducive to reactions of tertiary alkyl electrophiles. Indeed, we recently established that carbon–*boron* bond formation can be achieved by coupling tertiary halides with diboron reagents.[7] In this report, we expand the scope of cross-coupling reactions of unactivated tertiary alkyl electrophiles by describing the first method for accomplishing carbon–*carbon* bond formation with the aid of a group 10 catalyst (eq 1).

Early in this investigation, we decided to focus on organoboron reagents as coupling partners for two primary reasons. First, the Suzuki reaction is the most widely used cross-coupling method for the formation of C–C bonds.[8] Second, we have
employed organo-substituted 9-borabicyclo[3.3.1]nonane (9-BBN) reagents (in conjunction with an alkoxide activator) as partners in an array of Ni-catalyzed Suzuki couplings of *primary* and *secondary* electrophiles,[9] and we have further established that the conditions are not highly Brønsted-basic, because of complexation of the alkoxide to the trivalent borane.[4] The propensity of many tertiary alkyl electrophiles to undergo elimination under basic or acidic conditions is a significant impediment to cross-coupling this family of reaction partners.

When we applied our recently reported method for Ni-catalyzed carbon–*boron* bond formation with tertiary alkyl bromides to a corresponding Suzuki cross-coupling, we observed essentially no C–C bond formation (eq 2). Similarly, the conditions that we had developed for Suzuki arylations of primary and secondary alkyl bromides were not effective for tertiary bromides (<2% yield).[10]

Notwithstanding this result, we continued our pursuit of a method for the synthesis of all-carbon quaternary centers via the cross-coupling of unactivated tertiary halides. In view of the steric demand of tertiary electrophiles, we chose to focus on the use of smaller ligands. Ultimately, we determined that a Ni complex with the ligand 4,4′-di-*tert*-butyl-2,2′-bipyridine (**1**) serves as an effective catalyst for the coupling of 1-bromo-1-methylcyclohexane with phenyl-(9-BBN), furnishing the target compound in 88% yield (Table 1, entry 1). A variety of bioactive compounds, including oxycodone (OxyContin),[11] include an all-carbon quaternary center with one aryl substituent.

As illustrated in Table 1, in the absence of NiBr$_2$·diglyme, ligand **1**, or LiO*t*-Bu, little or no Suzuki cross-coupling of the unactivated tertiary alkyl bromide occurs (entries 2–4).

**Table 1. Suzuki Arylation of an Unactivated Tertiary Alkyl Bromide: Effect of the Reaction Parameters**

entry	variation from the "standard" conditions	yield (%)[a]
1	none	**88**
2	no NiBr$_2$·diglyme	<2
3	no **1**	8
4	no LiOt-Bu	<2
5	**2**, instead of **1**	72
6	**3**, instead of **1**	63
7	**4**, instead of **1**	7
8	KOt-Bu or NaOt-Bu, instead of LiOt-Bu	<2
9	toluene, instead of benzene	45
10	cyclohexane, instead of benzene	34
11	Et$_2$O, instead of benzene	13
12	1.8 equiv of (9-BBN)–Ph[b]	62
13	5% NiBr$_2$·diglyme, 5.5% **1**	53
14	0.1 equiv H$_2$O	89

[a]The yields were determined by GC analysis versus a calibrated internal standard and are averages of two experiments. [b]1.7 LiOt-Bu, 1.7 i-BuOH.
The use of 2,2′-bipyridine (**2**) or bathophenanthroline (**3**)[10a] rather than **1** as the ligand leads to a somewhat lower yield (entries 5 and 6). For every other Ni-catalyzed Suzuki reaction of 9-BBN reagents that we have described (couplings of primary and secondary electrophiles), a 1,2-diamine was the ligand of choice;[9] however, this is not the case for this Suzuki cross-coupling of a tertiary alkyl electrophile (entry 7). The counterion of the base plays a critical role in the efficiency of the coupling process (entry 8). C−C bond formation proceeds in lower yield in solvents such as toluene, cyclohexane, and Et$_2$O (entries 9−11), and the use of less organoborane or less catalyst leads to less product (entries 12 and 13). Finally, the cross-coupling is not highly moisture-sensitive (entry 14).

We established that this method can be applied to Suzuki reactions of an array of unactivated tertiary alkyl bromides, generating the desired C−C bond in good yield (Table 2).[12] Thus, both 1-bromo-1-methylcyclohexane and $tert$-butyl bromide

Table 2. Suzuki Cross-Couplings of Unactivated Tertiary Alkyl Bromides: Scope with Respect to the Electrophile

entry	tertiary alkyl bromide	yield (%)[a]
1		84
2		71 (84)[b]
3		70
4		53
5		86
6		57
7		76
8		67

[a]Yields of purified products (averages of two experiments). [b]Because of the volatility of the product, the yield in parentheses was determined by GC analysis with the aid of a calibrated internal standard.

are suitable substrates (entries 1 and 2), as is 3-bromo-3-ethylpentane, which is significantly more hindered (entry 3). Furthermore, a tertiary cyclobutyl bromide can be cross-coupled (entry 4). Importantly, functional groups such as an aromatic ring, ether, alkene, and primary alkyl chloride are compatible with this method for Suzuki cross-coupling of tertiary alkyl bromides (entries 5−8).

Although this method for cross-coupling of unactivated tertiary alkyl halides is versatile with respect to the electrophile (Table 2), it has limitations with respect to the nucleophile (Table 3).[13] Specifically, ortho- and para-substituted aryl-(9-BBN) reagents generally do not couple in useful yields; on the other hand, a range of meta-substituted compounds serve as suitable Suzuki cross-coupling partners. Fortunately, this set of products is particularly useful, since they are not available through direct Friedel−Crafts alkylation.

1-Iodoadamantane can also be cross-coupled, generating 1-aryladamantanes, a motif found in a number of pharmaceuticals (eq 3).[14−16] Furthermore, in a preliminary study, we determined that C−C bond formation can be achieved with an unactivated tertiary alkyl chloride as the electrophile (eq 4; yield determined by GC analysis).[16]

A possible mechanism for this Ni-catalyzed Suzuki cross-coupling, illustrated for the reaction of 1-bromo-1-methyl-cyclohexane with Ph-(9-BBN), is provided at the top of Figure 1.[4−6] As with our couplings of unactivated secondary alkyl halides, our initial mechanistic observations are consistent with a radical pathway for the oxidative addition of an unactivated tertiary halide to Ni. For example, when we conducted a Suzuki reaction in toluene rather than benzene, we obtained a significant amount of diphenylmethane (eq 5), likely due to H-atom abstraction from toluene by radical **B** to form a benzyl radical, which then enters the catalytic cycle (bottom of Figure 1).
Table 3. Suzuki Cross-Couplings of Unactivated Tertiary Alkyl Bromides: Scope with Respect to the Nucleophile

| entry	Ar	yield (%)[a]

2	3-i-Pr-C₆H₄	61
3	3-Ph-C₆H₄	74
4	3-OTBS-C₆H₄	57
5	3-Oi-Pr-C₆H₄	54

[a]Yields of purified products (averages of two experiments).
Furthermore, a Ni-catalyzed Suzuki reaction of a single diastereomer of a tertiary alkyl bromide leads to the formation of a mixture of diastereomeric cross-coupling products (eq 6). This observation can also be accommodated by a radical pathway for oxidative addition.

In conclusion, we have developed a method for Suzuki arylation of tertiary alkyl bromides, using commercially available catalyst components (NiBr₂·diglyme and 4,4′-di-*tert*-butyl-2,2′-bipyridine). To the best of our knowledge, this reaction is the

Figure 1. (top) Outline of a possible mechanism for the Ni/**1**-catalyzed Suzuki cross-coupling of an unactivated tertiary alkyl bromide. (bottom) Possible pathway for the formation of diphenylmethane when toluene is employed as the solvent (the early steps of the catalytic cycle are as illustrated at the top and have been omitted for simplicity).

first example of the use of organoboron reagents as cross-coupling partners with unactivated tertiary electrophiles as well as the first to employ a group 10 catalyst in cross-couplings of unactivated tertiary alkyl halides to form C−C bonds. In contrast with the umpolung approach to this bond construction (coupling of a tertiary organometallic reagent with an aryl halide), our method does not suffer from isomerization of the alkyl group.[17] Preliminary observations are consistent with a radical intermediate along the pathway of this new cross-coupling process. Additional studies directed at expanding the scope of this reaction and enhancing our understanding of the mechanism are underway.
