# Orienting effect of the cage addends: the case of nucleophilic cyclopropanation of $\boldsymbol{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ 

Marina G. Apenova, Olesya O. Semivrazhskaya, Eugenia V. Borkovskaya, Nikita M. Belov, Ilya N. Ioffe, Vitaliy Yu. Markov, Sergey I. Troyanov, Natalia S. Lukonina*, Lev N. Sidorov, and Alexey A. Goryunkov*

#### Abstract

C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\) was found to be a very promising substrate in the Bingel and the Bingel-Hirsch reactions combining perfect regioselectivity with much higher reactivity compared to its analogs. The reactions with diethyl malonate yield a single isomer of the monoadduct $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]$ and a single $\mathrm{C}_{2}$-symmetrical bisadduct $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]_{2}$. The Bingel-Hirsch variation is particularly interesting in that it additionally affords, in a similar regioselective manner, the unexpected alkylated derivatives $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}$ and $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}$. The novel compounds have been isolated and structurally characterized by means of ${ }^{1} \mathrm{H}$ and ${ }^{19} \mathrm{~F}$ NMR spectroscopy, single crystal X-ray diffraction. The mechanistic and regiochemical aspects of the reaction are explained with the aid of the DFT calculations.

## Introduction

Trifluoromethylated [70]fullerenes, a vast family of compounds with different arrangements of 2 to $20 \mathrm{CF}_{3}$ addends, ${ }^{[1-4]}$ show a potential for application in organic electronic devices. They remain chemically stable upon electron transfer and demonstrate good acceptor properties, their first reduction potentials varying within the range of -0.11 to 0.34 V vs $\mathrm{C}_{70}{ }^{0-1} .^{[2]}$ Moreover, it has been shown recently that the $\mathrm{CF}_{3}$ addition pattern of $C_{s}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}^{\ddagger}$ confers regioselectivity to a range of addition reactions. In particular, chlorination ${ }^{[5]}$ and cyanation ${ }^{[6]}$ of $C_{s}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ proceed selectively at its near-equatorial [5,6]double bond while nucleophilic addition of the bulky diethyl bromomalonate carbanion results in likewise selective cyclopropanation but now at more sterically accessible [6,6]bonds at the poles of the $\mathrm{C}_{70}$ cage. ${ }^{[7]}$ Similarly, the related $C_{1}$ $p^{7} m p-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{10}$ demonstrates regioselectivity towards its less sterically hindered pole in the reactions of nucleophilic alkylation ${ }^{[6,8]}$ and $[4+2]$-cycloaddition. ${ }^{[9]}$ Thus, further functionalization of trifluoromethylated fullerenes is a promising way to selectively introduce predefined regiochemistry and, consequently, chemical and electronic properties.

[^0]$C_{2}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$, the second most abundant isomer, is related to $C_{s}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ via relocation of only one $\mathrm{CF}_{3}$ group (Figure 1) ${ }^{[3,4,10]}$ However, this turns out to be enough to effect significant variations between their properties. $\mathrm{C}_{2}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ reveals a dramatic anodic shift of 0.34 V vs $\mathrm{C}_{70}{ }^{0 /-}$ in its first reduction potential compared to only 0.04 V in $\mathrm{C}_{\mathrm{s}}-\mathrm{p}^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} .{ }^{[2]}$ Undoubtedly, this difference in electronic properties should be reflected in the reactivity of the compounds, in particular, in the common organic functionalization reactions of fullerenes like nucleophilic addition and [4+2]-cycloaddition.

Figure 1. Schlegel diagrams of $C_{2^{-}}$and $C_{s^{-}} \mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ where large black circles denote $\mathrm{CF}_{3}$ groups. Marked otherwise are preferable addition sites of sterically unhindered (small black circles) and bulky (large white circles) addends as revealed by the experimental and theoretical findings of the present paper and of ref. 7 .

Here we present our first results on the nucleophilic addition to the $C_{2}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ (hereinafter $\left.\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\right)$. The Bingel reaction and its modification due to Hirsch were used to determine the most reactive sites in the molecule. We report the major reaction products obtained, the cycloadducts $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]_{n}, n=1-2$, and the less expected alkylated derivatives with $\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}$ addend.

## Results and Discussion

To prepare the precursory $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$, we used a two-step ampoule protocol. ${ }^{[4,10]}$ Initially, $\mathrm{C}_{70}$ was reacted with $\mathrm{CF}_{3}$ I in a sealed ampoule placed in a temperature gradient to give a mixture of $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{n}$ compounds ( $n=12-20$ ). Then, the mixture was ground with a further portion of $\mathrm{C}_{70}$ and heated in a glass ampoule at $450^{\circ} \mathrm{C}$ to give, via comproportionative transalkylation, the material enriched with $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$. The yield of the HPLC isolated individual $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ isomer was $8 \%$.

Nucleophilic cyclopropanation of $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ was carried out following the two conventional alternative routes: (i) the Bingel reaction ${ }^{[11]}$ with diethyl bromomalonate in the presence of $t$-BuOK as a base and (ii) the variation of the Bingel reaction involving diethyl malonate in the presence of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) as a base and $\mathrm{I}_{2}$ (reported by Diederich et al. ${ }^{[12]}$ and labeled as Bingel-Diederich reaction hereinafter) or $\mathrm{CBr}_{4}$ (suggested by Hirsch et al. ${ }^{[13]}$ and designated as Bingel-Hirsch reaction hereinafter) as a source of halogen. The Bingel reaction starts with nucleophilic addition of a stabilized $\alpha$-halogenated carbanion to the fullerene cage, which is followed by intramolecular nucleophilic substitution to yield a cyclopropane moiety (Scheme 1).

Scheme 1. The Bingel reaction mechanism.

In all cases, according to the HPLC data, the conversion of $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ was largely complete within several minutes. The product compositions, however, were different (Figure 2a). The Bingel reaction gave a single major product while the BingelHirsch modification afforded at least three in comparable yields (and the same set of major products was observed upon replacement of $\mathrm{CBr}_{4}$ with iodine under Bingel-Diederich conditions, see Figure $S 2$ in the SI ). Compared to $C_{\mathrm{s}}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ and $C_{1}-p^{7} m p-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{10}$ where the Bingel-Hirsch reaction requires several hours to complete, $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ demonstrates much higher reactivity. Apparently, its stronger electronwithdrawing properties translate into higher affinity to the anionic bromomalonate intermediate.

The reaction products (compounds I-IV in the increasing order of retention times) and unreacted $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ (compound V) were isolated from the reaction by means of multistep HPLC using toluene and toluene-hexane mixtures (1:1 and 3:7 v/v) as eluents. The molecular compositions of the isolated compounds as determined by means of MALDI MS are shown in Figure $2 b$ and in Table 1. Compounds IV and II common to both reaction variations were found to be the expected mono- and biscyclopropanated adducts of $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$. Products III and I specific to the Bingel-Hirsch reaction turned out to be the alkylated rather than cyclopropanated $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}$ and the mixed $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}$.

Unexpected observation of the alkylated products I and III under the Bingel-Hirsch conditions prompted us to investigate a similar system with malonate and DBU but without any halogen compounds. Remarkably, $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ still turned out to be reactive and selectively gave compound III (Figure 2a, bottom), i.e. the product of alkylation without cycloaddition. For the pristine fullerenes, we observed no interaction (see Figure S3,4 in SI ), which correlates with the lack of alkylated products already under the Bingel-Hirsch and Bingel-Diederich conditions.

The MALDI mass spectra (negative ion mode) of the cyclopropanated adducts IV and II were dominated by the
molecular anions $\quad \mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]^{-}$and $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]_{2}{ }^{-}$(Figure $2 b$, left and Figure $\mathrm{S} 1 d$ in SI ), respectively, with several minor signals due to the $\mathrm{CF}_{3}$ loss and impurities. Such MS behavior, which is quite typical for the Bingel derivatives of trifluoromethylated fullerenes, ${ }^{[7,8]}$ demonstrates high stability of the doubly linked malonate moieties under the MALDI conditions. On the contrary, compound III with its singly linked addends gave rise to $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} \mathrm{H}^{-}$as the major MS signal (Figure $2 b$, right) accompanied by much weaker peaks of $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}{ }^{-}$and $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]^{-}$. Interpretation of $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} \mathrm{H}^{-}$as a fragment of the missing molecular anion $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}^{-}$was supported by detection of an additional weak metastable peak due to fragmentation in the drift region. Accordingly, $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]^{-}$is the pseudomolecular ion formed via deprotonation, which is typical for fullerene compounds with cage-linked hydrogens. ${ }^{[14]}$ Compound I demonstrated the same principal fragmentation channels as III, i.e. Ioss of $\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]$ or a proton (see Figure S1c in SI ).

Figure 2. a) HPLC traces of the product mixtures from the Bingel, BingelHirsch reactions of $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$, and the reaction with diethyl malonate and DBU only (Cosmosil Buckyprep, 4.6 mm I.D. $\times 25 \mathrm{~cm}$, toluene:hexane=1:1 v./v., $1 \mathrm{~mL} \mathrm{~min}{ }^{-1}$ ). b) Negative ion MALDI mass spectra of compounds IV and III with enlarged major peaks and theoretical isotopic pattern of $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)\right]^{-}$.

[a] Cosmosil Buckyprep column, 4.6 mm I.D. $\times 25 \mathrm{~cm}, 290 \mathrm{~nm}, 25^{\circ} \mathrm{C}$, at flow rate of $2 \mathrm{~mL} \mathrm{~min}{ }^{-1}$. [b] According to MS MALDI data. [c] According to HPLC trace integration. [d] $1 \mathrm{~mL} \mathrm{~min}^{-1}$.

Interestingly, the previously reported Bingel-Hirsch reactions of $C_{\mathrm{s}}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ and $C_{1}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{10}$ have not been observed to yield any non-cyclized products. ${ }^{[7,8]}$ It is likely that the peculiarity of the $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ case is due to its higher electron affinity. We will discuss the possible formation mechanisms of the alkylated compounds I and III in more detail in the respective section below.

## Structural determination of the cyclopropanated adducts II and IV

Slow evaporation of a toluene solution of II gave pink crystalline material. Single crystal X-ray diffraction study using synchrotron radiation revealed formation of a $C_{2}$-symmetric bisadduct $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]_{2}$. Cyclopropanation occurs at the symmetrically equivalent [6,6]-bonds $\boldsymbol{a}$ and $\boldsymbol{a}^{\prime}$ ' at the poles of the fullerene cage (see Figure 3 and Table 2 for bond labeling) and results in elongation of these bonds from 1.391(4) $\AA$ in the parent trifluoromethylated fullerene ${ }^{[10]}$ to $1.582(4)$ and $1.588(5) \AA$, which is typical for methanofullerenes. ${ }^{[15]}$ The lengths of neighboring $\mathrm{C}-\mathrm{C}$ bonds are also slightly elongated from $\sim 1.45$ to ~1.48 Å.

Figure 3. X-ray structure of the $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]_{2}$ bisadduct (II). Two projections of the molecule are shown.

NMR spectroscopic data for the compound II are fully consistent with the X-ray structure. The ${ }^{19} \mathrm{~F}$ NMR spectrum contains four $\mathrm{CF}_{3}$ multiplets of equal intensity (Figure 4a). The quartet signal at $\delta_{F}-69.6 \mathrm{ppm}$ with $J_{\text {FF }} 10.6 \mathrm{~Hz}, 1.3 \mathrm{ppm}$ upfield with respect to the parent $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$, corresponds to the terminal pair of $\mathrm{CF}_{3}$ groups $(\mathbf{A})$. The other unresolved quartet ( $\mathbf{D}$ ) is characteristic of the central pair of $\mathrm{CF}_{3}$ addends, and the two multiplet signals in between are due to the rest two pairs of $\mathrm{CF}_{3}$ groups. The ${ }^{1} \mathrm{H}$ NMR spectrum of II consists of two $A B X_{3}$ spin systems of equal intensity due to the two inequivalent pairs of ethoxy groups with diasteretopic methylene protons (Figure 4b). The $\mathrm{CH}_{3}$ protons give rise to the triplet signals at $\delta_{H} 1.35$ and 1.41 ppm while the protons of the methylene moieties can be found at $\delta_{H} 4.48,4.45,4.39$ and 4.35 ppm ( A and B doublets of quartets). Rather large spacing between the $\mathrm{CF}_{3}$ and the malonate moieties makes their mutual influence on the NMR pattern quite weak.

The structure of the $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]$ monoadduct (IV) has been determined on the basis of the ${ }^{19} \mathrm{~F}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopic data and DFT calculations. The ${ }^{19} \mathrm{~F}$ NMR spectrum of compound IV consists of four $\mathrm{CF}_{3}$ signals of equal and two of doubled intensity (Figure 4c), which indicates the lack of molecular symmetry. The two quartet signals at $\delta_{F}-68.8$ and -69.1 ppm ( $\mathrm{J}_{\text {FF }} 11.0$ and 10.4 Hz ) can be attributed to the two terminal $\mathrm{CF}_{3}$ groups ( $\mathbf{H}$ and $\mathbf{A}$ ), now inequivalent. The ${ }^{1} \mathrm{H}$ spectrum of IV is quite similar to that of II in that it comprises two $\mathrm{ABX}_{3}$ systems due to the two ethoxy moieties (Figure 4d). The methyl protons are observed at $\delta 1.32$ and 1.41 ppm (triplets, ${ }^{3} J_{\mathrm{HH}} 7.1 \mathrm{~Hz}$ ) while the methylene ones - at $\delta_{H} 4.45$ and 4.49 ppm (AB quartets of quartets, ${ }^{2} J_{\mathrm{HH}} 10.6 \mathrm{~Hz},{ }^{3} \mathrm{~J}_{\mathrm{HH}} 7.1 \mathrm{~Hz}$ ).

As was shown previously, regioselectivity in the nucleophilic cyclopropanation of $C_{s}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ and $C_{1}-p^{7} m p-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{10}$ correlates with the relative formation energy of the anionic intermediates and cyclopropanated products. ${ }^{[7,8]}$ This correlation is likely based on the Bell-Evans-Polanyi (BEP) relationship
between the activation energy and the enthalpy for a series of isomeric reactions. Applicability of BEP-based kinetic model for prediction of isomeric composition in fullerene chemistry was recently verified on example of trifluoromethylation of fullerenes possessing rich isomeric and compositional product complexity. ${ }^{[16]}$ In order to determine the possible cyclopropanation position in IV, we have carried out the DFT relative energy calculations of all theoretically possible isomeric intermediates $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CBr}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]^{-}$and final compounds $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]$. The most energetically favorable intermediates and cycloadducts are listed in the Table 2.

Table 2. The DFT relative energies of the most energetically favorable isomers of $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]$ and their anionic precursors $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CBr}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]^{-}$.
Anionic
intermediate Monoadduct
[a] In the Schlegel diagram of $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ (left) black circles denote the $\mathrm{CF}_{3}$ groups, the $\boldsymbol{a}-\boldsymbol{g}$ indices denote the bonds at which cycloaddition occurs and the indices with subscript numerals denote the possible anionic intermediate attachment sites.
to be the most stable. The next stable isomeric bisadduct with a and $\boldsymbol{b}$ attachment of the malonate moieties is only $11 \mathrm{~kJ} \mathrm{~mol}^{-1}$ higher; however, similarly to the monoadduct case, its anionic intermediate $\boldsymbol{b}_{1}$ was observed $30+\mathrm{kJ} \mathrm{mol}^{-1}$ above $\boldsymbol{a}_{1}$. Thus, regioselective formation of II and IV is governed by the same energy-based BEP criteria.

## Structure of the alkylated compounds <br> $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}$ (III) and $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}(\mathrm{I})$

The structure of the $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}$ (III) was deduced from the ${ }^{19} \mathrm{~F}$ and ${ }^{1} \mathrm{H}$ NMR data. The ${ }^{19} \mathrm{~F}$ NMR spectrum contains eight signals of the equal intensity within the range of 58 to -72 ppm demonstrating inevitable asymmetry of the compound (Figure 5a). All eight signals were unambiguously attributed to corresponding $\mathrm{CF}_{3}$ groups $\mathbf{A}-\mathbf{H}$ on the basis of the ${ }^{19} \mathrm{~F}$ COSY NMR spectrum (see Figure $S 5$ in the SI). Most importantly, the quartet $\mathbf{A}$ at $\delta_{F}-71.8\left(J_{F F} 12.1 \mathrm{~Hz}\right)$ and the doublet of quartets $\mathbf{H}$ at $\delta_{F}-63.9 \mathrm{ppm}\left(J_{F F} 13.2 \mathrm{~Hz}\right.$ and $J_{H F} 2.7$ Hz ) are clearly due to the terminal $\mathrm{CF}_{3}$ groups. To understand the structure of III, it was material to find out, which of the protons gives rise to the doublet splitting of $\mathbf{H}$. The ${ }^{1} \mathrm{H}$ NMR spectrum of III contained two already familiar $\mathrm{ABX}_{3}$ patterns due to the ethoxy groups plus a broadened singlet signal at $\delta_{H} 5.91$ ppm and a quartet signal at $\delta_{\mathrm{H}} 4.91 \mathrm{ppm}\left(J_{\mathrm{HF}} 2.7 \mathrm{~Hz}\right)$ (Figure $5 b$ ). Knowing the typical chemical shift ranges for various types of protons in the fullerene compounds, ${ }^{[14,17]}$ the quartet signal is to be assigned to the malonate $\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}$ proton while the singlet - to the $\mathrm{C}_{70}-\mathrm{H}$ one. Thus, $\mathrm{CF}_{3}$ group $\mathbf{H}$ interacts with the malonate proton, which can be possible only if the two groups are attached in the same ring of the $\mathrm{C}_{70}$ cage. The broadening of the singlet at 5.91 ppm is also indicative of interaction of the cage linked hydrogen with, most probably, some $\mathrm{CF}_{3}$ group and, consequently their close proximity to each other. Although the said coupling does not give rise to any additional splitting in the ${ }^{19} \mathrm{~F}$ spectrum, a considerable upfield shift of the signal A by 3.5 ppm with respect to the parent $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ can be viewed as an evidence that the interaction involves the fluorine atoms of $\mathbf{A}$.

As one can see, the most favorable anionic intermediates involve the $\boldsymbol{a}_{1}$ and $\boldsymbol{a}_{\mathbf{2}}$ sites and both lead to the likewise most favorable cycloadduct $\boldsymbol{a}$. Even though the six alternative cycloadduct isomers $\boldsymbol{b}-\boldsymbol{g}$ are characterized by comparatively low relative energy, their anionic precursors can be found no less than $30 \mathrm{~kJ} \mathrm{~mol}^{-1}$ above $\boldsymbol{a}_{1}$. Thus, our quantum chemical data predicts the nucleophilic cyclopropanation of $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ to occur at the [6,6]-bond a. This conclusion, being perfectly corroborated by the above discussed bisaddict II with attachment to $\boldsymbol{a}$ and $\boldsymbol{a}^{\prime}$, makes the structural assignment of IV unambiguous.

It was interesting to verify the validity our theoretical analysis by applying it to the possible isomeric bisadducts based on IV. The detailed results, which perfectly agree with the experimental findings, are given in Tables S4 and S5 of the SI. Briefly, both the experimental compound II and its $\boldsymbol{a}_{1}$ intermediate turned out

Figure 5. ${ }^{1} \mathrm{H}$ and ${ }^{19} \mathrm{~F}$ NMR spectra and Schlegel diagram of alkylated product $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}$ III.

Theoretically, formation of III can occur via two alternative pathways: through either $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]^{-}$or $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} \mathrm{H}^{-}$ anionic intermediates. In the former case, $\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]^{-}$anions form in minor quantities in a proton-exchange equilibrium between DBU and non-brominated diethyl malonate, alongside with more stable $\left[\mathrm{CBr}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]^{-}$, and then become captured by the electron-withdrawing $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ molecules. Subsequent protonation will afford the final product III. Alternatively, $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}{ }^{-\bullet}$ anions form upon single electron transfer from DBU and detach a hydrogen atom from a malonate molecule to give a closed shell $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} \mathrm{H}^{-}$intermediate. $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} \mathrm{H}^{-}$will then attach the dehydrogenated ${ }^{\circ} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}$ radical and return the extra electron to neutral $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ or $\mathrm{DBU}^{+}$. Obviously, formation of III without $\mathrm{CBr}_{4}$ means that the reduction-hydrogen transfer pathway is implicated anyway. However, it was interesting to analyze, whether it would still remain predominant in presence of $\mathrm{CBr}_{4}$. Therefore, we have carried out a theoretical analysis of the possible intermediates for both reaction pathways in question.

As shown in Table 3, the most stable isomeric $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]^{-}$intermediates have the malonate moiety attached at the sites $a_{1}$ or $b_{1}$. Unlike the case of bulkier bromomalonate intermediate (see Table 2), the two structures are virtually isoenergetic. The NMR-based conclusion regarding proximity to a terminal $\mathrm{CF}_{3}$ group would clearly suggest $\boldsymbol{b}_{\mathbf{1}}$, but $a_{1}$ has an obvious advantage of better steric accessibility. Therefore, formation of III via the malonate pathway would likely result in a mixture of two isomers rather than a single one. On the contrary, the hydrogen transfer pathway clearly favors the hydrogenated intermediate $\boldsymbol{h}_{1}$ over all the others. Furthermore, hydrogen attachment to the site $\boldsymbol{h}_{1}$ should give rise to an interaction with a terminal $\mathrm{CF}_{3}$ group as suggested by the NMR data. Thus, formation of III as a single isomer of $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}$ demonstrates that the hydrogen
transfer pathway must be at least much faster than the malonate one.

To analyze the regiochemistry of alkylation of the $\boldsymbol{h}_{1}$ isomer of $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} \mathrm{H}^{-}$, we have considered the energetics of the isomeric $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2} \mathrm{H}^{-}\right.$anions with varied site of malonate attachment. The experimental isomer III was found to be $18 \mathrm{~kJ} \mathrm{~mol}^{-1}$ more stable than any alternative structures (see Table S10 in the SI). Thus, we arrive at the structure of III as shown in Figure 5, which demonstrates perfect agreement with the NMR observations. Note that III is isostructural to a number of $\mathrm{C}_{70}$ derivatives including $\mathrm{C}_{70} \mathrm{X}_{10}, \mathrm{X}=\mathrm{H}, \mathrm{Cl}, \mathrm{Br}, \mathrm{CH}_{3},{ }^{[18]}$ as well as some bisadducts of $\mathrm{C}_{\mathrm{s}}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}{ }^{[5,6]}$ its highly favorable addition pattern separating the initial spherical $\pi$-system of $\mathrm{C}_{70}$ into the two disjoint corannulene-based subsystems of 28 and 32 electrons.

Table 3. The DFT relative energies of most energetically favorable isomers of anionic intermediates $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]^{-}$and $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} \mathrm{H}^{-}$

|  | Anionic intermediate $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} R, R=, \Delta E, \mathrm{~kJ} \mathrm{~mol}^{-1}$ |  |  |
| :---: | :---: | :---: | :---: |
|  | at site | $\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}$ | H |
|  | $h_{1}$ | 28 | 0 |
|  | $b_{1}$ | 0 | 71 |
|  | $a_{1}$ | 2 | 37 |
|  | $a_{2}$ | 18 | 46 |
|  | $\mathbf{e}_{2}$ | 18 | 42 |
|  | $d_{2}$ | 25 | 41 |
|  | $k_{1}$ | 69 | 22 |

Turning now to the compound $\mathbf{I}$, its low quantity made us impossible to acquire sufficiently accurate NMR data. However, we have acquired its ${ }^{19} \mathrm{~F}$ NMR spectrum which turned out to be quite similar to that of III and the ${ }^{1} \mathrm{H}$ spectrum containing a signal at 5.8 ppm due to the cage-linked hydrogen. Thus, the NMR and MALDI MS data available predict $\mathbf{I}$ to be a mixed $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}$ adduct with hydrogen and $\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}$ attachment like in III and cyclopropanation most probably as in II and IV. Indeed, our DFT data demonstrates this hypothetic structure of $I$ to be the most favorable, $11 \mathrm{~kJ} \mathrm{~mol}^{-1}$ below the next stable isomer.

Orienting effect of trifluoromethylation and the electronic structure aspects
As is shown above, while the bulky $\alpha$-bromomalonate carbanion tends to attach to the poles of the $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$, the more compact species like non-brominated malonate carbanion may prefer the equatorial region of the molecule. The closely related $\mathrm{C}_{\mathrm{s}}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ is known to show the similar trends both for the bulkier $\alpha$-bromomalonate carbanion ${ }^{[7]}$ and the smaller groups of Cl and $\mathrm{CN} .{ }^{[5,6]}$ This is different from pristine $\mathrm{C}_{70}$ where both
nucleophilic addition and cycloaddition preferably occur at the polar region, ${ }^{[11,14,19]}$ (the only exclusion is a highly thermodynamically stable equatorial adduct $C_{2 v}-\mathrm{C}_{70}\left(\mathrm{CH}_{2}\right)$ obtainable only under extreme conditions via pyrolysis of $\mathrm{C}_{70}$ with $\mathrm{CH}_{4}$ at $1100{ }^{\circ} \mathrm{C}$ or via the Krätschmer-Huffman method in the presence of methane ${ }^{[20]}$ due to poor kinetics). So far, we have demonstrated that the products reported in the present paper can be predicted on the basis of the energetic criteria. It is interesting to find out, whether our findings correlate with the common reactivity criteria like orbital localization approaches.

The eight $\mathrm{CF}_{3}$ groups drastically alter the geometry of the equatorial region of the molecule. Thus, bond lengths of equatorial naphthalenoid moiety of $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ fall within much narrower range of 1.40-1.42 $\AA^{[10]}$ (except for the bond $c$ of $1.460(3) \AA$ A , see Figure 6) compared to the pristine $\mathrm{C}_{70}$ (1.476(16) $\AA$ for $\boldsymbol{c}$ and 1.37-1.45 $\AA$ for the rest of the bonds $\left.{ }^{[21]}\right)$. In the related $C_{s}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$, the near-equatorial [5,6]-bond $\boldsymbol{d}$ became likewise shortened to $1.418(6) \AA^{[3]}$ from 1.437(9) $\AA$ in the pristine $\mathrm{C}_{70} \cdot{ }^{[21]}$ Pronounced shortening of the bonds $\boldsymbol{b}$ and $\boldsymbol{d}$ in $\boldsymbol{C}_{2^{-}}$and $C_{s}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$, respectively, reflects the increase in their bond orders and, consequently, in their reactivity toward cycloaddition, as well as nucleophilic, electrophilic, and radical addition.

Figure 6. LUMO and LUMO +1 localization in $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ (left) and $C_{\mathrm{s}^{-}}$ $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ (right). The bonds are labelled according to Table 2 and to ref. $7\left(\mathrm{C}_{\mathrm{s}}\right.$ isomer).

The DFT-calculated LUMO localization in $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ and $\mathrm{C}_{\mathrm{s}}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ is shown in Figure 6. Both molecules have the highest LUMO contributions at the carbon atoms in ortho- and para-positions with respect to the terminal $\mathrm{CF}_{3}$ groups and, to a somewhat lesser extent, in the polar pentagons. Hence, the
orienting effects of the LUMO localization should direct the smaller anionic species to the equatorial sites, mostly to the para-positions with respect to the $\mathrm{CF}_{3}$ addends since the orthopositions are strongly screened, while the bulky nucleophiles will attack the poles of the fullerene cage. Thus, the equatorial belts of the $\mathrm{CF}_{3}$ groups effect such alteration of the electronic structure of $\mathrm{C}_{70}$ that the LUMO induces regioselective nucleophilic addition to the equatorial region of the molecule.

The difference in the overall addition patterns between the compounds I-V turns out to have quite discernible effect on the electronic properties as evidenced by the UV/Vis spectra shown in Figure 7. Mono- and biscyclopropanation of $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ withdraws, respectively, two and four electrons from the $\pi$ system, which results in a blue shift of the first absorption band by ca. 55 nm per each cyclopropane moiety. Transition to a disjoint $\pi$-system in III has much deeper consequences - the first absorption band blueshifts by as much as 220 nm with respect to $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$. A further 35 nm shift is observed in I in accordance with reduction of $\pi$-system during cyclopropanation of III. Noteworthy, the experimental data show a good correlation with the calculated HOMO-LUMO gap (Table 4).

Figure 7. UV/Vis spectra of compounds I-V (toluene as a solvent).

Reduction of the $\pi$-system also leads to a significant decrease in the calculated electron affinity (EA). EA values drop from 3.1 eV for the parent $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ to 2.8 and 2.6 eV for mono- and bis-cycloadduct, respectively, and even further for the compounds III and I. Note the 0.3 eV difference between the EA of compounds IV and III despite the same overall size of the conjugated system, which can be regarded as a measure of the effect of its partition into the two disjoint fragments in III.

## Conclusions

The increased electron affinity of $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ endows it with enhanced reactivity toward nucleophilic addition compared to its analogs. Moreover, it also gives rise to the alternative reaction pathways in the Bingel-Hirsch reaction affording alkylation alongside with cyclopropanation. What is even more interesting, it further enables pure alkylation when one completely removes any sources of halogen, and it involves the equatorial, normally less reactive, region of the $\mathrm{C}_{70}$ cage. Together with remarkable regioselectivity due to the orienting effects of the $\mathrm{CF}_{3}$ groups, this gives a family of novel fullerene derivatives employable as acceptors in charge transfer systems.
In this regard, the malonate moieties can provide a very convenient way of chemically linking these compounds to the donor substances.

It is to be noted that, compared to other classes of electron withdrawing fullerene derivatives, the trifluoromethylated
fullerene compounds are particularly advantageous due to stability of the $\mathrm{CF}_{3}$ groups towards nucleophilic substitution. Hence, the Bingel and Bingel-Hirsch functionalization of the trifluoromethylated fullerene compounds may evolve in a promising approach in the field of design of novel fullerene materials. Of special interest would be a broader comparison of reactivity and regioselectivity as a function of the addition pattern and electron affinity.

## Experimental Section

## General information

Mass spectrometry. The negative ion MALDI mass spectra were recorded using a Bruker AutoFlex II (Bruker Daltonik GmbH) Rf-TOF mass spectrometer equipped with an $\mathrm{N}_{2}$ laser ( $337 \mathrm{~nm}, 2.5 \mathrm{~ns}$ pulse). Trans-2-[3-(4-tert-butylphenyl)-2-methyl-2-propenylidene]malononitrile (DCTB, $\geq 98 \%$, Sigma-Aldrich) was used as a matrix, matrix-to-analyte molar ratio in probes being above 1000/1. The high resolution positive ion ESI mass spectra were registered using a LTQ Orbitrap XLTM instrument (resolving power above 50000). The acetonitrile (HPLC grade) with $0.1 \%$ of formic acid was used as a solvent.

High performance liquid chromatography. HPLC analyses were carried out using an Agilent 1100 System equipped with a diode array detector (DAD) and a temperature-controlled Cosmosil Buckyprep 4.6 mm I.D. $\times 25 \mathrm{~cm}$ column (Nacalai Tesque, Inc.). HPLC separation was carried out using a Waters 1500 chromatographic system equipped with a dual wavelength UV/Vis detector and Cosmosil Buckyprep 10 mm I.D. $\times 25 \mathrm{~cm}$ column (Nacalai Tesque, Inc.). Toluene (99.8\%, Khimmed, Russia), hexane ( $99.7 \%$, Khimmed, Russia) and mixtures thereof were used as eluents. The UV/Vis spectra of the toluene solutions were obtained via a DAD in the 290-950 nm range with resolution of 2 nm .

NMR spectroscopy. ${ }^{1} \mathrm{H},{ }^{19} \mathrm{~F}$, and ${ }^{13} \mathrm{C}$ NMR spectra were recorded at $400.3,376.5$ and 150 MHz , respectively, using a Bruker Avance-400 spectrometer. The samples were dissolved in chloroform-d and spiked with small amounts of hexafluorobenzene ( $\delta_{F}-162.9 \mathrm{ppm}$ ) and TMS ( $\delta_{H}$ and $\delta_{\mathrm{C}} 0.0 \mathrm{ppm}$ ) as internal standards.

Quantum chemical calculations. The complete sets of the cyclopropanated mono- ( 41 structures) and bisadducts (1571 structures), i.e. $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]_{n}$ with $n=1$ or 2 , considered herein include all theoretically possible isomers with cycloaddition to the pairs of adjacent $s p^{2}$ atoms in $C_{2}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$. The complete sets of the anionic intermediates $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} R^{-}, \quad R=\mathrm{H}, \quad-\mathrm{CBr}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}, \quad-\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}$, (31 structures for each) include all inequivalent additions to the $s p^{2}$ atoms of the $C_{2}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ molecule. In the cases of attachment of the $-\mathrm{CBr}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}$ and $-\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}$ moieties, we additionally performed preliminary conformational analysis with respect to the internal rotation at the AM1 level of theory. See the SI for further details.

Initially, molecular geometry of the each structure in question was optimized using the TINKER 4.2 molecular mechanic package with MM2 force field. ${ }^{[22]}$ In the next step, the geometry was refined at the AM1 level of theory with the use of the Firefly 8.1 software ${ }^{[23]}$ partly based on the GAMESS (US) source code. ${ }^{[24]}$ This was followed by single point DFT calculations and final DFT optimizations of the subsets of most stable structures. The latter were carried out with the use of the PRIRODA v. 6 software implementing efficient RI approximation. ${ }^{[25]}$ PBE exchangecorrelation functional ${ }^{[26]}$ and a built-in basis set of triple zeta quality with
(11s6p2d)/[6s3p2d] contraction scheme for first row atoms and $(5 s 1 p) /[3 s 1 p]$ for hydrogens were used.

X-ray crystallography. Single crystals of $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]_{2}$ II suitable for X-ray diffraction analysis were obtained by slow evaporation of solvent from an HPLC purified fraction. Synchrotron X-ray data were collected at 100 K at the BESSY storage ring (BL14.2, PFS, Berlin, Germany) using a MAR225 CCD detector, $\lambda=0.9050 \AA$. Structure was solved and anisotropically refined using the SHELX package. ${ }^{[27]}$ $\mathrm{C}_{92} \mathrm{H}_{20} \mathrm{~F}_{24} \mathrm{O}_{8}$ : monoclinic, $P 2_{1} / n, a=14.4300$ (9) $\AA, b=21.615(2) \AA, c=$ 20.064(1) $\AA, \beta=92.027(6)^{\circ}, V=6254.1(8) \AA^{3}, Z=4, \mathrm{R}_{1}(F) / w \mathrm{R}_{2}\left(F^{2}\right)=$ 0.072/0.162 for 13121/11862 reflections and 1234 parameters. One $\mathrm{CF}_{3}$ group is disordered over two positions around a $\mathrm{C}-\mathrm{CF}_{3}$ bond. Two $\mathrm{CO}_{2}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)$ groups are disordered over two positions each with an occupancy ratio of $0.535 / 0.465(4)$. CCDC 1043212 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data request/cif.

## Synthesis of $C_{2}-\boldsymbol{p}^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$

Fullerene $\mathrm{C}_{70}$ (Fullerene-center, $99.8 \%$; 50 mg ) was loaded into a glass ampoule and an excess of $\mathrm{CF}_{3} 1$ ( $\mathrm{P} \& \mathrm{M}$-Invest, $98 \%$; ca. 1 mL ) was then condensed into it under cooling with liquid nitrogen. The sealed ampoule was placed into a gradient furnace at $420^{\circ} \mathrm{C}$ for 72 h . As was evidenced by MALDI MS, the resulting mixture consisted of higher trifluoromethylated compounds with 12 to $20 \mathrm{CF}_{3}$ addends. Annealing of the said mixture ( 40 mg ) with pristine $\mathrm{C}_{70}(15 \mathrm{mg})$ in a sealed glass ampoule at $450{ }^{\circ} \mathrm{C}$ for 40 h yielded a mixture of lower $\mathrm{CF}_{3}$ derivatives, with 2 to $10 \mathrm{CF}_{3}$ groups. Isolation of the individual $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ isomer was carried out by means of HPLC using a Cosmosil Buckyprep 10 mm I.D. $\times 25 \mathrm{~cm}$ column and toluene as an eluent (flow rate $4.6 \mathrm{~mL} \mathrm{~min}^{-1}$ ). Additional HPLC purification of the isolated fraction with the use of the $1: 1(\mathrm{v} / \mathrm{v})$ toluene-hexane mixture as an eluent gave ca. 4 mg of pure individual $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$. Over 10 mg of the pure $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ have been accumulated after several synthetic runs, which was sufficient for further chemical reactions.

Compound V, $\boldsymbol{C}_{2}-\boldsymbol{p}^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}, \mathbf{1 , 4 , 1 1 , 1 9 , 3 1 , 4 1 , 5 1 , 6 0 - \mathrm { C } _ { 7 0 } ( \mathrm { CF } _ { 3 } ) _ { 8 } : t _ { R } 2 . 3 8}$ min (Cosmosil Buckyprep 4.6 mm I.D. $\times 25 \mathrm{~cm}$, toluene, $2 \mathrm{~mL} \mathrm{~min}^{-1}$ ); ${ }^{19} \mathrm{~F}$ NMR ( $376.5 \mathrm{MHz}, \mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, \mathrm{C}_{6} \mathrm{~F}_{6}$ ): $\delta=-61.10\left(\mathrm{~m}, 6 \mathrm{~F} ; \mathrm{CF}_{3}\right),-61.64$ $\left(\mathrm{m}, 6 \mathrm{~F} ; \mathrm{CF}_{3}\right),-62.66\left(\mathrm{~m}, 6 \mathrm{~F} ; \mathrm{CF}_{3}\right),-68.32 \mathrm{ppm}(\mathrm{q}, \mathrm{J}(\mathrm{F}, \mathrm{F})=11.5 \mathrm{~Hz}, 6 \mathrm{~F}$; $\mathrm{CF}_{3}$ ); UV/Vis (toluene): $\lambda_{\max }=328,370,432,514,552,612,654,670 \mathrm{~nm}$; MALDI MS: $m / z$ (\%): 1392.0 (100) [M].

## The Bingel-Hirsch reaction with $C_{2}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$

Diethyl malonate (Acros Organics, 99+\%; $4.3 \mu \mathrm{~L}, 28 \mu \mathrm{~mol}$ ), carbon tetrabromide (Acros Organics, $9.3 \mathrm{mg}, 28 \mu \mathrm{~mol}$ ) and 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU; Acros Organics, 98\%; $4.2 \mu \mathrm{~L}, 28$ $\mu \mathrm{mol})$ in toluene ( $400 \mu \mathrm{~L}$ ) were stirred at $40^{\circ} \mathrm{C}$ for 20 min . In each synthetic run, $100 \mu \mathrm{~L}$ of the said solution was added to the solution of $C_{2^{-}}$ $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}(7.5 \mathrm{mg}, 5 \mu \mathrm{~mol})$ in 10 mL of toluene. Then an additional portion of DBU ( $1 \mu \mathrm{~L}, 7 \mu \mathrm{~mol}$ ) in toluene ( $100 \mu \mathrm{~L}$ ) was added dropwise under stirring. The reaction mixture was stirred at room temperature for further 15 min and then filtered through silica using toluene as an eluent. The four fractions containing reaction products I-IV as well as starting $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} \mathrm{~V}$ were isolated by means multi-step HPLC separation (Cosmosil Buckyprep 10 mm I.D. $\times 25 \mathrm{~cm}$ column and toluene-hexane, $1: 1$ and $3: 7 \mathrm{v} / \mathrm{v}$, as eluents with flow rate of $4.6 \mathrm{~mL} \mathrm{~min}^{-1}$ ).

## The Bingel reaction with $C_{2}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$

1. Synthesis of the diethyl bromomalonate. Several drops of the liquid bromine were added to diethyl malonate ( $30 \mathrm{~mL}, 0.198 \mathrm{~mol}$ ) in chloroform ( 30 mL ) and the mixture was then briefly heated to $80^{\circ} \mathrm{C}$ to initiate the reaction. Then an additional amount of bromine ( 10.2 mL , 0.198 mol ) was added dropwise at room temperature. The brown-red reaction mixture was then refluxed until coming to a residual pale color stable in time. The cooled mixture was washed 5 times with 15 mL of aqueous $\mathrm{Na}_{2} \mathrm{CO}_{3}(5 \%)$, the organic layer was then separated and evaporated at $40^{\circ} \mathrm{C}$ under low pressure. Finally, the resulting diethyl bromomalonate was purified by distillation at 10 Torr, b.p. $106{ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR (400.3 MHz, $\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, \mathrm{TMS}$ ): $\delta=4.81$ (s, 1H; CH), 4.29 (q, $\left.{ }^{3} \mathrm{~J}(\mathrm{H}, \mathrm{H})=7.15 \mathrm{~Hz}, 4 \mathrm{H} ; \mathrm{CH}_{2}\right), 1.30 \mathrm{ppm}\left(\mathrm{t},{ }^{3} \mathrm{~J}(\mathrm{H}, \mathrm{H})=7.15 \mathrm{~Hz}, 6 \mathrm{H} ; \mathrm{CH}_{3}\right)$; ${ }^{13} \mathrm{C}$ NMR ( $150 \mathrm{MHz}, \mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}$, TMS): $\delta=164.60(\mathrm{C}=\mathrm{O}), 63.25\left(\mathrm{CH}_{2}\right)$, $42.44(\mathrm{CH}), 13.90 \mathrm{ppm}\left(\mathrm{CH}_{3}\right)$; HRMS (ESI): m/z calcd for $\mathrm{C}_{7} \mathrm{H}_{11} \mathrm{BrO}_{4}+\mathrm{H}^{+}$: $238.9913\left[\mathrm{M}^{\left.+\mathrm{H}^{+}\right] ; \text {found: } 238.9907 .}\right.$
2. The Bingel reaction. To a solution of $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}(4.9 \mathrm{mg}, 3.5 \mu \mathrm{~mol})$ and diethyl bromomalonate ( $0.8 \mu \mathrm{~L}, 4.9 \mu \mathrm{~mol}$ ) in toluene, potassium tertbutoxide ( $0.55 \mathrm{mg}, 4.9 \mu \mathrm{~mol}$ ) in toluene ( 1 mL ) was added. The reaction was stirred at $40^{\circ} \mathrm{C}$ for 20 min and then filtered through silica using toluene as eluent. Two fractions containing compounds II and IV as well as starting $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8} \mathbf{V}$ were isolated via HPLC (Cosmosil Buckyprep 10 mm I.D. $\times 25 \mathrm{~cm}$ column and toluene-hexane, $1: 1 \mathrm{v} / \mathrm{v}$, as an eluent with flow rate of $4.6 \mathrm{~mL} \mathrm{~min}^{-1}$ ).

## Alkylation of $C_{2}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$ with diethyl malonate in the presence of DBU

DBU ( $0.2 \mu \mathrm{~L}, 1.3 \mu \mathrm{~mol}$ ) in toluene ( $20 \mu \mathrm{~L}$ ) was added to the solution of $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}(2 \mathrm{mg}, 1.3 \mu \mathrm{~mol})$ in toluene ( 3 mL ) and the resulting mixture was stirred at $40^{\circ} \mathrm{C}$ for 5 min under an inert atmosphere. Then diethyl malonate ( $0.2 \mu \mathrm{~L}, 1.3 \mu \mathrm{~mol}$ ) in toluene ( $20 \mu \mathrm{~L}$ ) was added. After 10 min of further stirring at $40^{\circ} \mathrm{C}$, few drops of $\mathrm{CF}_{3} \mathrm{COOH}$ were added, and the reaction mixture was filtered through silica using toluene as an eluent. According to the HPLC, MALDI MS, and UV/Vis spectra, there was only a single reaction product, which was identified as compound III.

## The Bingel-Diederich reaction with $C_{2}-p^{7}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$

To the solution of $C_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}(0.9 \mathrm{mg}, 0.6 \mu \mathrm{~mol})$ in toluene $(1.5 \mathrm{~mL})$, DBU ( $0.09 \mu \mathrm{~L}, 0.6 \mu \mathrm{~mol}), \mathrm{I}_{2}(0.15 \mathrm{mg}, 0.6 \mu \mathrm{~mol})$ and diethyl malonate $(0.09 \mu \mathrm{~L}, 0.6 \mu \mathrm{~mol})$ in toluene ( $60 \mu \mathrm{~L}$ ) were added. The reaction mixture was stirred at $40^{\circ} \mathrm{C}$ for 10 min under an inert atmosphere. Then a few drops of $\mathrm{CF}_{3} \mathrm{COOH}$ were added, and the mixture was filtered through silica using toluene as an eluent. According to HPLC, MS MALDI and UV/Vis data, the product composition was the same as in the reaction under the Bingel-Hirsch conditions.

Compound $\mathrm{I}, \mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]\left[\mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right] \mathrm{H}: t_{\mathrm{R}} 5.1 \mathrm{~min}$ (Cosmosil Buckyprep 4.6 mm I.D. $\times 25 \mathrm{~cm}$, toluene-hexane, $3: 7(\mathrm{v} / \mathrm{v}), 1 \mathrm{~mL} \mathrm{~min}{ }^{-1}$ ); ${ }^{19} \mathrm{~F}$ NMR ( $564.7 \mathrm{MHz}, \mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, \mathrm{C}_{6} \mathrm{~F}_{6}$ ): $\delta=-57.7\left(\mathrm{~m}, 3 \mathrm{~F} ; \mathrm{CF}_{3}\right),-61.0$ (m, 3F; CF ${ }_{3}$ ), -61.5 (m, 3F; CF ${ }_{3}$ ), $-62.4\left(\mathrm{~m}, 3 \mathrm{~F} ; \mathrm{CF}_{3}\right),-62.6\left(\mathrm{~m}, 3 \mathrm{~F} ; \mathrm{CF}_{3}\right)$, $-64.3\left(\mathrm{~m}, 3 \mathrm{~F} ; \mathrm{CF}_{3}\right),-64.5\left(\mathrm{q}, \mathrm{J}(\mathrm{F}, \mathrm{F})=13.8 \mathrm{~Hz}, 3 F ; \mathrm{CF}_{3}\right),-71.9 \mathrm{ppm}(\mathrm{q}$, $J(F, F)=12.1 \mathrm{~Hz}, 3 F ; \mathrm{CF}_{3}$ ); UV/Vis (toluene): $\lambda_{\max }=365,390,416 \mathrm{~nm}$; MALDI MS: $m / z(\%): 1551.0$ (100) [ $\left.M-\left\{\mathrm{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right\}^{-}\right], 1709.0$ (6) [M].

Compound II, $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}\left[\mathbf{C}\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}\right]_{2}: t_{\mathrm{R}} 5.4 \mathrm{~min}$ (Cosmosil Buckyprep 4.6 mm I.D. $\times 25 \mathrm{~cm}$, toluene-hexane, $\left.3: 7(\mathrm{v} / \mathrm{v}), 1 \mathrm{~mL} \mathrm{~min}^{-1}\right) ;{ }^{1} \mathrm{H}$ NMR ( $400.3 \mathrm{MHz}, \quad \mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, \mathrm{TMS}$ ): $\delta=4.48 \quad\left(\mathrm{dq},{ }^{3} \mathrm{~J}(\mathrm{H}, \mathrm{H})=7.1 \mathrm{~Hz}\right.$, $\left.{ }^{2} J(\mathrm{H}, \mathrm{H})=10.8 \mathrm{~Hz}, 2 \mathrm{H}, 2 \mathrm{CH}_{2}\right), 4.45\left(\mathrm{dq},{ }^{3} J(\mathrm{H}, \mathrm{H})=7.1 \mathrm{~Hz},{ }^{2} \mathrm{~J}(\mathrm{H}, \mathrm{H})=10.8 \mathrm{~Hz}\right.$, $2 \mathrm{H} ; 2 \mathrm{CH}_{2}$ ), $4.39\left(\mathrm{dq},{ }^{3} \mathrm{~J}(\mathrm{H}, \mathrm{H})=7.1 \mathrm{~Hz},{ }^{2} \mathrm{~J}(\mathrm{H}, \mathrm{H})=10.8 \mathrm{~Hz}, 2 \mathrm{H} ; 2 \mathrm{CH}_{2}\right), 4.35$ (dq, $\left.{ }^{3} J(H, H)=7.1 \mathrm{~Hz},{ }^{2} J(\mathrm{H}, \mathrm{H})=10.8 \mathrm{~Hz}, 2 \mathrm{H} ; 2 \mathrm{CH}_{2}\right), 1.41\left(\mathrm{t},{ }^{3} \mathrm{~J}(\mathrm{H}, \mathrm{H})=7.1 \mathrm{~Hz}\right.$, $\left.6 \mathrm{H} ; 2 \mathrm{CH}_{3}\right), 1.35 \mathrm{ppm}\left(\mathrm{t},{ }^{3} \mathrm{~J}(\mathrm{H}, \mathrm{H})=7.1 \mathrm{~Hz}, 6 \mathrm{H} ; 2 \mathrm{CH}_{3}\right) ;{ }^{19} \mathrm{~F}$ NMR ( 376.5 MHz ,
$\mathrm{CDCl}_{3}, 25^{\circ} \mathrm{C}, \mathrm{C}_{6} \mathrm{~F}_{6}$ ): $\delta=-61.52\left(\mathrm{~m}, 6 \mathrm{~F} ; \mathrm{CF}_{3}\right),-62.33$ (br. sept, $\left.J(\mathrm{~F}, \mathrm{~F})=11.0,6 \mathrm{~F} ; \mathrm{CF}_{3}\right),-62.50\left(\mathrm{~m}, 6 \mathrm{~F} ; \mathrm{CF}_{3}\right),-69.60 \mathrm{ppm}(\mathrm{q}, J(\mathrm{~F}, \mathrm{~F})=10.6$ $\mathrm{Hz}, 6 \mathrm{~F} ; \mathrm{CF}_{3}$ ); UV/Vis (toluene): $\lambda_{\max }=365,412,471,518,558 \mathrm{~nm}$; MALDI MS: $m / z$ (\%): 1639.0 (5) $\left[M-\mathrm{CF}_{3}{ }^{-}\right], 1652.3$ (11) $\left[M^{*}-\mathrm{CF}_{3}{ }^{-}\right], 1708.0$ (100) [ $M^{+}$].

## Acknowledgements

The authors are grateful Sergey A. Sokolov for HRMS analysis. This work was partially supported by the Russian Foundation for Basic Research (projects nos. 12-03-31513, 13-03-00311, 15-03-05083) and the Ministry of Education and Science of the Russian Federation (project MD-5540.2013.3). The reported study was supported by the Supercomputing Center of Lomonosov Moscow State University. ${ }^{[28]}$

## Notes

$\ddagger$ Hereinafter, the isomeric names are given in the following format: "symmetry-notation of the addittion pattern-composition", e.g. $C_{\mathrm{s}}-p$ " $\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$. Abbrevations used in the notation for the addition patterns: $p$, para, and $m$, meta, denote $\mathrm{C}_{6}\left(\mathrm{CF}_{3}\right)_{2}$ hexagon with 1,4 - and 1,3 -situated $\mathrm{CF}_{3}$ groups, respectively; superscript denotes the number of similar edgesharing fragments in a chain, a discontinuity in an addition pattern is denoted by comma.

## Entry for the Table of Contents

## FULL PAPER

Acceptor derivatized fullerene substrates can exhibit enhanced reactivity and regioselectivity in the important organic reactions. We report Bingel and Bingel-Hirsch functionalization of $\mathrm{C}_{2}-\mathrm{C}_{70}\left(\mathrm{CF}_{3}\right)_{8}$, which affords rapid and LUMOdirected regioselective formation of both conventional cyclopropanated and unusual alkylated products. The mechanistic and regiochemical aspects of the reaction are explained with the aid of the DFT calculations.
