Transformations

ABSTRACT

Reactions of quinazoline **1** with indole, pyrogallol and 1-phenyl-3-methylpyrazol-5-one in the presence of acid led to C-4 adducts **2**, **3** and **5**. Adduct **4** is formed by heating **1** with 1,3-dimethylbarbituric acid without acid catalysis. 1-Phenyl-3-methylpyrazol-5-one reacts with **1** without acid catalysis to form dipyrazolylmethane **6**. 4-Chloroquinazoline **8** reacts with 1-phenyl-3-methylpyrazol-5-one to form 4-(1-phenyl-3-methyl-5-oxopyrazol-4-yl) quinazoline **9** and dipyrazolylmethane **6**. Heating **8** with 2-methylindole leads to the formation of 4-(2-methylindol-3-yl) quinazoline **10** and tris(2-methylindol-3-yl)methane **11**.

The quinazoline moiety is an important part of many natural alkaloids.[1] Compounds with diverse biological activities (hypotonic, antiallergenic, antibacterial and anthelminthic) have been found among quinazoline derivatives.[2] The search for antagonists of folic and isofolic acids as cellular mitosis inhibitors has received significant attention recently.[3,4] Antitumour[2] and radioprotective[5,6] quinazoline derivatives have also been synthesized.

In acidic medium, unsubstituted quinazoline was found to form a covalent hydrate at the N3=C4 bond.[7] Similarly, 3-methylquinazolinium iodide undergoes addition of alkyl- and arylamines and indoles to form 4-substituted-3,4-dihydroquinazolines.[8]

In this work, we found that unsubstituted quinazoline **1**, on heating with indole in boiling butanol for 2 h in the presence of trifluoroacetic acid, afforded the stable salt 4-(indol-3-yl)-3,4-dihydroquinazoline **2** (Scheme 1). 4-(2,3,4-Trihydroxyphenyl)-3,4-dihydroquinazoline **3** was obtained on heating quinazoline with pyrogallol in boiling ethanol for 2 h in the presence of hydrochloric acid. Products **2** and **3** precipitated after the reaction mixture had been cooled and were isolated in pure state by filtration.

We observed quantitative formation of 4-(1,2,3,4,-tetrahydro-6-hydroxy-1,3-dimethyl-2,4-dioxopyrimidin-5-yl)-3,4-dihydroquinazoline **4** when recording the ^{1}H NMR spectrum of a solution of the reaction of an equimolar mixture of quinazoline **1** and 1,3-dimethylbarbituric acid in dimethyl sulfoxide at room temperature. We also isolated adduct **4** in crystalline state after heating the starting components in *n*-butanol for a short time.

Heating quinazoline **1** with 1-phenyl-3-methylpyrazol-5-one in boiling *n*-butanol in the presence of trifluoroacetic acid for 2 h produced 4-(1-phenyl-3-methyl-3-oxopyrazol-4-yl)-3,4-dihydroquinazoline trifluoroacetate **5**. At the same time, the known 4,4-methylidene-bis(1-phenyl-3-methylpyrazol-5-one) **6**[9] was obtained by heating quinazoline **1** for 10 h with a threefold excess of 1-phenyl-3-methylpyrazol-5-one in boiling *n*-butanol without acidic catalysis. After cooling the reaction mixture, product **6** was filtered off and recrystallized from *n*-butanol (35% yield).

Dipyrazolylmethane **6** may be formed via nucleophilic attack of 1-phenyl-3-methylpyrazol-5-one at the C-2 atom of **1** followed by pyrimidine ring-opening and attack of a second pyrazolone followed by elimination (Scheme 2).

4-Chloroquinazoline **8** (Scheme 3) reacts with a threefold molar excess of 1-phenyl-3-methylpyrazol-5-one in dimethylsulfoxide in the presence of triethylamine to form the substitution product, namely, 4-(1-phenyl-3-methyl-5-oxopyrazol-4-yl)-quinazoline **9** (45% yield) along with dipyrazolylmethane **6** (6% yield).

Product **9** was isolated by recrystallization of the precipitate obtained from the cooled reaction mixture from ethanol. Treatment of the mother liquor from the recrystallization of **9** with water gave dipyrazolylmethane **6**. The formation of product **6** indicates that, in this case, competitive nucleophilic attack at the C-2 atom of quinazoline occurs along with nucleophilic substitution of the halogen.

The halogen substitution product 4-(2-methylindol-3-yl)-quinazoline **10**, and the known tris(2-methylindol-3-yl)-methane

11[10] were obtained by heating 4-chloroquinazoline **8** with a threefold molar excess of 2-methylindole in boiling ethanol for 1 h. Tris(indolylmethane) **11** was filtered off from the cooled reaction mixture (10% yield). The mother liquor was dried and **10** was isolated from the solid residue by thin layer chromatography on silica (R_f = 0, chloroform).

The formation of tris(indolylmethane) **11** results from nucleophilic attack of indole on the C-2 atom of 4-chloroquinazoline **8** followed by further transformation via Scheme 4.

The high reactivity of 4-chloroquinazoline towards C-nucleophiles is due, most likely, to the autocatalytic effect of the hydrogen chloride evolved upon substitution.

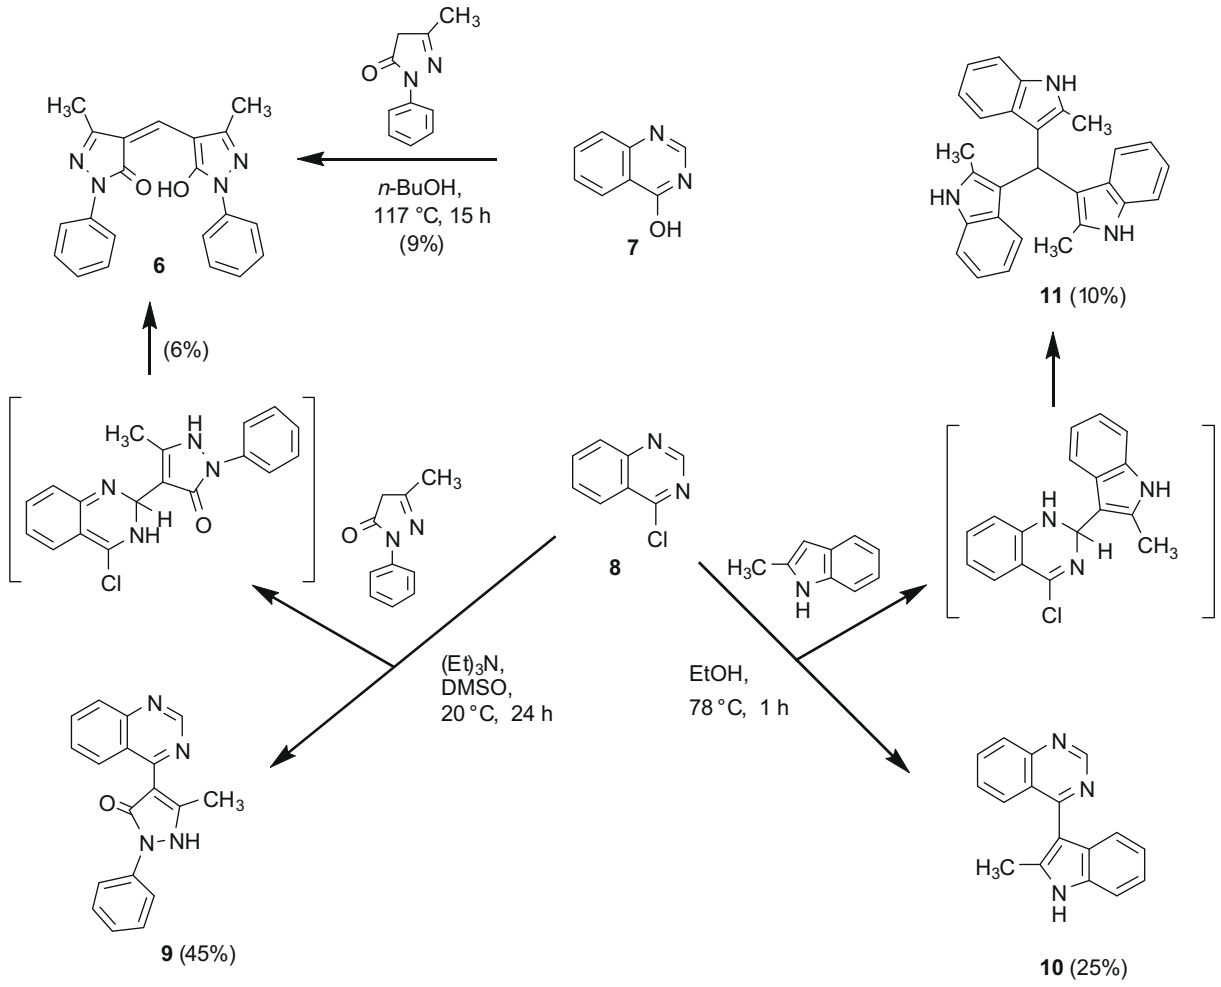
Heating of product **9** in boiling *n*-butanol in the presence of water also affords dipyrazolylmethane **6** in 14% yield. Product **6** was isolated by filtration after cooling the reaction mixture. The formation of dipyrazolylmethane **6** is preceded, most likely, by nucleophilic substitution of the pyrazole residue for the hydroxy group.

Initially formed pyrazolone attacks 4-hydroxyquinazoline at the C-2 atom. Next, the heterocycle is cleaved, and a second attack of pyrazolone occurs, leading eventually to product **6** (Scheme 5).

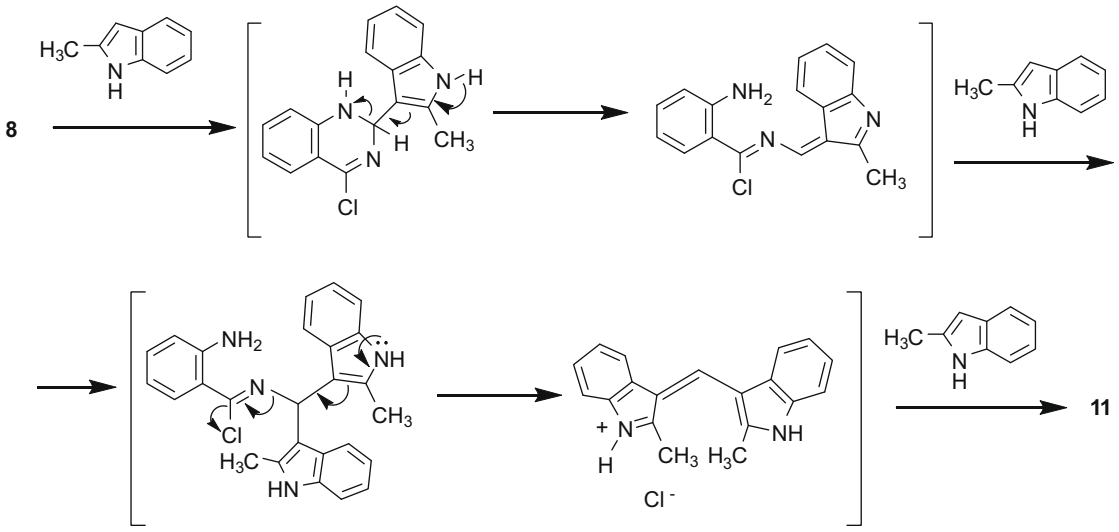
The validity of this assumption is confirmed by the formation of dipyrazolylmethane **6** (9% yield) on heating an authentic sample of 4-hydroxyquinoline **7** with 1-phenyl-3-methylpyrazol-5-one in boiling *n*-butanol for 15 h.

Characteristic properties for adducts **2-5** are signals for the H-4 proton in the range 6.0–6.5 ppm.[11] Note that in the 2D-NOESY spectrum of compounds **4**, detection of the cross-peak connecting the proton nucleus at C-4 (heterocyclic fragment) with the proton at C-5 (aromatic cycle) that unequivocally confirms the structures of these C-4 adducts (Fig. 1).

The electron impact mass spectrum of adduct **2** exhibited an intense peak due the molecular ion at *m/z* 247. At the same time, only molecular ions of the starting components and products of their decomposition were detected in the EI spectra of adducts **3**, **4** and **5**.



Scheme 3.



Scheme 4.

It is noteworthy that these unusual transformations result from nucleophilic attack on the C-2 atom of quinazoline without external activation (catalysis). The described transformations open opportunities for the synthesis of new, potentially biologically active products and have fundamental value in quinazoline chemistry.
