Reactions of 2-aminophosphonium salts with methyliodide in the presence of sodium hexamethyldisilazide(NaHMDS) gave N-methylated phosphonium salts which reacted benzaldehyde and isocyanates in the presence of NaHMDS to give ω -N-methyl-aminoalkenes and ω -N-phosphinoylamide.

Keywords: cyclic aza-ylide; Wittig reaction; alkylation; acylation

INTRODUCTION

Cyclic phosphonium salts have two nucleophilic carbons on α -positions of phosphorus atom. Recently, we reported tandem Wittig^[1] and tandem Michael-Wittig reactions^[2] of five and six membered phosphonium salts using these two nucleophilic points. On the other hand, iminophosphoranes are versatile reagents for synthesis of imines and nitrogen containing heterocycles^[3]. Furthermore, cyclic 2-azaphosphonium salts have different kinds of nucleophilic atoms, carbon and nitrogen as shown in Figure 1.

Previously, we showed a synthesis and some applications of 2-azaphosphonium salts for preparations of heterocycles using the different kinds of theses nucleophilic centers^[4]. In our continuing studies on the utilities of

cyclic phosphonium salts to organic synthesis, we wish to report tandem reactions of 2-amino phosphonium salts.

RESULTS AND DISCUSSION

A reaction of five membered cyclic aza-yilde 2a, generated from aminophosphonium salt 1a in the presence of sodium hexamethyldisilazide (NaHMDS), with methyliodide gave ω -N-methylaminophosphine oxide 3a in 70 % yield. An attempt to isolate N-methylated aminophosphonium salts 4a,b failed. Similarly, a reaction of six membered aza-ylide 2b gave 3b in 73% yield. When one more equivalent of NaHMDS and benzaldehyde were added to the reaction mixture in the same reaction vessel, N-phosphinoylaminoalkenes 6a,b were isolated in 25% and 61% yields, respectively. The geometry of olefin position in 6a,b were determined by their nmr spectra. The coupling constant of the olefin protons was 10.7Hz for 6a, and 12Hz for 6b which suggests a cis configuration.

Similarly, reactions of six membered **5b** with isocyanates gave Wittig products **8**, ω -N-phosphinoylamino-amides, as major products, whereas when using the five membered **5a**, ω -phosphinoylureas **9** were the only isolated products (Scheme 2). The compound **8** would come from a Wittig reaction of ylide with isocyanate followed by hydrolysis of ketenimine. On the other hand, the product **9** would come from the ring opening of ylide **5a** to form the intermediate **A** which would react with isocyanate. The structures of **8** and **9** were determined by spectral data. Especially, in the ¹³C nmr spectra of amides **8**, the carbonyl group appeared at 172– 173 ppm. On the other hand, the chemical shifts of urea carbonyls were

observed at 156–159 ppm. These results are consistent with the observations that the carbonyl resonance of amides, N-methylacetamide, and N,N-dibuty-lacetamide, appear at 171.6 and 169.1 ppm, and that those of ureas such as urea and dimethylurea, appear at 161.2 and 160.3 ppm, respectively^[5].

These results clearly support the intermediate formation of ylides **5a,b.** The difference of the reactivities between five and six membered ylides, **5a** and **5b**, would be due to the stabilities of the rings. Because the ring strain of five-membered-5a would be much larger than that of six-membered-5b, the ylide 5a would be decomposed immediately to form the intermediate A which reacts with electrophiles as shown in Scheme 3. The more stable six-membered ylide 5b would react with electrophiles to form the Wittig products.

SCHEME 3

Furthermore, a reaction of 2a with benzoylchloride in the presence of an equimolar amount of NaHMDS gave amide 10 in 77% yield. Using two equimolar amounts of benzoylchloride and NaHMDS, however, amide 10 and N,N-disubustituted amide 11 were obtained in 15% and 36% yields, respectively. The product 11 would be formed by the reaction of the intermediate A with benzoyl chloride.

SCHEME 4

In summary, cyclic 2-azaphosphonium salts have different kinds of nucleophilic atoms, carbon and nitrogen, and we showed that the two kinds of nucleophilic sites on the six-membered salt could be used efficiently for the formation of carbon-nitrogen and carbon-carbon bond. In the case of five membered salt, because of the lability of the phosphorus ylide formed in the second step, the ring opening reaction has occurred.
