### Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

**Abstract**

An analysis of Antibody-Drug Conjugate Payload manufacturing has revealed that the majority of the cost is associated with the use of high-containment facilities for the latter stages of the synthesis. To make a significant reduction in the Cost of Goods (CoGs), a new approach to route design has been introduced which focusses on minimizing the number of steps that require high-containment. This approach has been exemplified in a new synthesis of tesirine, including the first application of a ring-closing copper (I)/TEMPO aerobic oxidation to the pyrrolobenzodiazepine ring system, affording a 60% reduction in CoGs.

## Introduction

Antibody-Drug Conjugates (ADCs) are an important new class of oncology therapeutics, combining a tumor-targeting antibody with a cell-killing cytotoxic drug (payload).<sup>1</sup> Significant activity in this new field has resulted in the approval of brentuximab vedotin (Adcetris)<sup>2</sup> in 2011 and trastuzumab emtansine (Kadcyla)<sup>3</sup> in 2013, followed by the 2017 approvals of inotuzumab ozogamicin (Besponsa) and gemtuzumab ozogamicin (Mylotarg). Extensive clinical programs continue to evaluate potential commercial candidates, with further launches expected in the next few years.

The cytotoxic drugs employed as ADC payloads are typically based on natural products, exemplified by the auristatins<sup>4</sup> (based on dolastatin 10)<sup>5</sup> which have been used in Adcetris, and the maytansinoids<sup>6</sup> (based on maytansine)<sup>7</sup> used in Kadcyla.

1  
2  
3  
4 These molecules have high synthetic complexity, and their discovery and development  
5  
6  
7 has required significant contributions from the field of synthetic organic chemistry.  
8  
9  
10 Recent interest in new payloads has been focused on the pyrrolbenzodiazepines  
11  
12  
13 (PBDs),<sup>8</sup> which have been employed by Seattle Genetics, Stemcentrx, ADC  
14  
15  
16  
17 Therapeutics and MedImmune in their clinical ADC programs. The leading PBD linker-  
18  
19  
20 payload is tesirine (1, SG3249),<sup>9</sup> which is utilized in rovalpituzumab tesirine (Rova-T)<sup>10</sup>  
21  
22  
23 for the treatment of small cell lung cancer and loncastuximab tesirine (Lonca-T)<sup>11</sup> for the  
24  
25  
26  
27 treatment of B-cell non-Hodgkin lymphoma,<sup>11</sup> as well as in a range of further programs.  
28  
29  
30  
31 The initial synthesis of tesirine has been described previously,<sup>12</sup> as well as a detailed  
32  
33  
34 description of the synthetic development and scale-up of this route.<sup>13</sup>  
35  
36  
37

38  
39 As part of a detailed review of the route following the delivery of a 60g batch of  
40  
41  
42 tesirine, a full analysis of costs, timings and yields was completed to provide greater  
43  
44  
45 insight into areas for further development. Overall the original route is high yielding and  
46  
47  
48 has been successfully scaled-up, delivering multiple campaigns on multi-gram scales.  
49  
50  
51  
52 However, one area that the analysis highlighted was the cost breakdown between the  
53  
54  
55 chemistry steps performed in high-containment and standard facilities. High-  
56  
57  
58  
59  
60

1  
2  
3 containment is required for molecules that are cytotoxic and these specialist facilities  
4  
5  
6  
7 include features such as controlled air handling (including airlocks); controlled entry and  
8  
9  
10 exit of materials and personnel; specialist containment equipment (gloveboxes for  
11  
12  
13 solids, fume hoods/downflow booths for liquids) and planned cleaning and  
14  
15  
16  
17 decontamination systems. The use of such facilities is expensive and is a major  
18  
19  
20  
21 contributor to any campaign of a cytotoxic linker-payload.  
22  
23

24 For the original route to tesirine (Scheme 1), the final 8 out of the 34 synthetic steps  
25  
26  
27 are performed in a high containment facility (Figure 1). An analysis of the 60g delivery  
28  
29  
30  
31 revealed that this part of the synthetic campaign accounted for 90% of the cost of  
32  
33  
34  
35 campaign, with the initial 26 synthetic steps, performed in standard facilities, only  
36  
37  
38 accounting for 10% of the cost. This cost breakdown is in direct contrast to the  
39  
40  
41  
42 synthesis of a comparable non-cytotoxic molecule prepared using a route of similar  
43  
44  
45  
46 synthetic length and complexity, where the early part of the manufacturing is more  
47  
48  
49 expensive due to the need to use pilot-plant or kilo-lab facilities, whereas the latter steps  
50  
51  
52 can be completed in laboratory glassware.  
53  
54  
55

1  
2  
3  
4 This analysis clearly demonstrated that in order to make a significant impact on the  
5  
6  
7 cost of manufacturing tesirine, a reduction in the use of high-containment facilities would  
8  
9  
10 be required. To facilitate this, a new approach to route design has been introduced,  
11  
12  
13 focusing on reduction in the number of synthetic steps requiring high-containment  
14  
15  
16 facilities. Route design typically focusses on number of steps, convergency and yield,  
17  
18  
19 but for the large-scale preparation of cytotoxic payloads (and more generally for  
20  
21  
22 cytotoxic molecules), a focus on reduction in the number of steps requiring high-  
23  
24  
25 containment facilities should be a key consideration, both in terms of cost reduction and  
26  
27  
28 improving campaign flexibility and timings.  
29  
30  
31  
32  
33

34  
35 With the completion of the analysis, work was initiated looking to redesign the route  
36  
37  
38 with a focus on reduction in the number of steps requiring high-containment facilities.  
39  
40  
41  
42 Success in this approach offered the potential to afford a new, more efficient route in  
43  
44  
45 terms of cost, time and synthetic efficiency.

## Results and Discussion

The key structural features imparting cytotoxicity to the PBDs are well understood,<sup>14</sup> with a requirement for the A-, B- and C-rings of the molecule to be in place. In the original synthesis of tesirine, high-containment facilities were required during construction of the two halves of molecule and for the dimerization and subsequent stages (Figure 1). For the half of the molecule containing the dipeptide trigger, high containment was required for the oxidative cyclisation of **4** to **5** to afford the completed ABC ring system. For the other half of the molecule, a number of the tricyclic intermediates were tested and found to be non-toxic, but attachment of the 5-carbon linker to **6** to afford **7** required high-containment. In total, 8 stages needed to be undertaken in high-containment facilities.

To minimize the number of cytotoxic intermediates and thus the number of steps requiring high-containment facilities we reasoned that construction of the B-rings should be moved to as late as possible in the synthesis. To this end, we considered what would be suitable final steps for the synthesis. Oxidative cyclisation of both B-rings was

considered as the final step, but based on previous experience this chemistry would be incompatible with the sensitive maleimide group. It was thus decided to retain the alloc-deprotection and attachment of the PEG-maleimide linker as the final two steps, and investigate the oxidative cyclisation of both B-rings as the antepenultimate step (Scheme 2). Thus, starting from the previously reported mono-protected dimer (**9**),<sup>15</sup> the alloc-protected Val-Ala-PAB trigger was attached affording **10**, following which the TBS protecting groups were removed affording diol (**11**).

Scheme 2. Demonstration of the closure of the B-rings as the antepenultimate step.

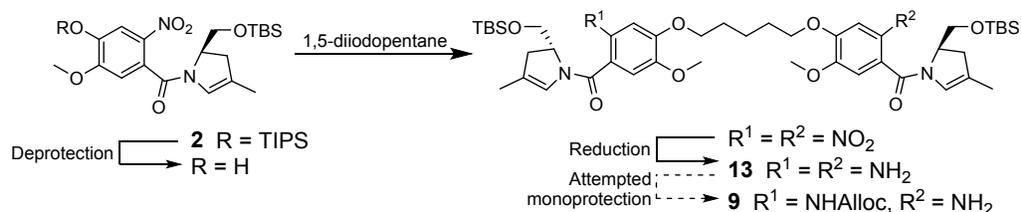

Identifying effective oxidation conditions which would reliably deliver full cyclisation of both B-rings proved challenging. A wide-ranging initial screen showed low conversion with methods such as Swern,<sup>16</sup> Pfitzner-Moffat<sup>17</sup> and TEMPO/bleach,<sup>18</sup> but over-

1  
2  
3 oxidation with Dess\_Martin periodinane<sup>19</sup> and sulfur trioxide pyridine.<sup>20</sup>  
4  
5  
6  
7 TEMPO/bis(acetoxy)iodobenzene (BAIB)<sup>21</sup> or Stahl conditions ([Cu(MeCN)<sub>4</sub>]OTf, bpy,  
8  
9  
10 TEMPO, NMI)<sup>22</sup> were identified as the most promising options to get clean oxidative  
11  
12  
13 cyclisation of both B-rings. Attempted optimization of the TEMPO/BAIB showed  
14  
15  
16  
17 significant variability in the reaction and in the purity of the product, thus development  
18  
19  
20  
21 was directed to the use of Stahl conditions. Work focused on optimizing the equivalents  
22  
23  
24  
25 of reagents and ensuring that effective air-sparging was scalable. These conditions  
26  
27  
28 gave consistent and selective oxidations, with >95% conversion to the required product  
29  
30  
31 (12). This intermediate then intercepts the original route for the final two steps to  
32  
33  
34  
35 tesirine (Figure 1).  
36  
37

38 This changed route requires 3 steps to be completed in high-containment facilities, in  
39  
40  
41 contrast to the original route which requires 8 steps. To quantify the full benefits of this  
42  
43  
44  
45 revised route in terms of cost reduction, it was decided to develop the required  
46  
47  
48  
49 transformations to allow the newly demonstrated final steps to be used in a  
50  
51  
52 manufacturing campaign.  
53  
54  
55  
56  
57  
58  
59  
60

To this end, efficient routes to bis-TBS ether (**10**) were evaluated starting from the key intermediate **2**. Synthesis via the mono-protected dimer (**9**) was evaluated in detail (Scheme 3), where **2** was deprotected and alkylated with 1,5-diiodopentane following which nitro-reduction afforded a bis-aniline (**13**). For this approach to demonstrate synthetic efficiency, an efficient mono-alloc protection of **13** was required. This transformation was investigated in detail, including varying reagents, stoichiometries and conditions (including the use of biphasic systems), but no significant improvement could be made on the statistical ratio of 1:2:1 bis-aniline:mono-alloc protected product:bis-alloc protected product. Thus, separate preparation of two halves of the PBD-dimer was targeted as a more efficient method of preparing **10**.

Scheme 3. Approach to bis-TBS ether (**10**) via bis-aniline (**13**).

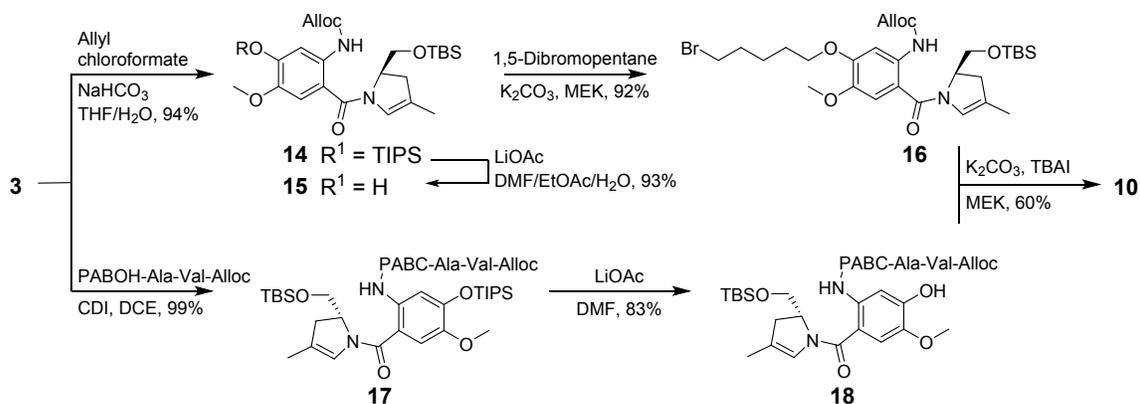

1  
2  
3 Key intermediate (**2**) was reduced to aniline (**3**) using zinc and ammonium acetate in  
4  
5  
6 ethanol. Alternative reagents for this transformation were evaluated and the use of  
7  
8  
9  
10 dithionate initially looked promising, but more detailed analytical work showed that  
11  
12  
13 although effective for completing the reduction, the reagent also caused O- to N-  
14  
15  
16 migration of the TIPS group. Thus the original zinc conditions were adopted and the  
17  
18  
19 resultant material used without further purification. From this intermediate (**3**), work  
20  
21  
22 started on the separate functionalisation of the two halves of the dimer. For the alloc-  
23  
24  
25 protected half of the dimer, the alloc protecting group was introduced using allyl  
26  
27  
28 chloroformate and sodium hydrogen carbonate in aqueous THF and the product (**14**)  
29  
30  
31 used without further purification. Investigation into removal of the TIPS-group  
32  
33  
34 demonstrated that transformation could be achieved using potassium  
35  
36  
37 carbonate/methanol as well as the more standard lithium acetate/DMF, although the  
38  
39  
40 latter conditions were used for manufacturing as they gave a cleaner reaction profile.  
41  
42  
43 The product phenol (**15**) was purified using a silica plug. Introduction of the 5-carbon  
44  
45  
46 linker was then evaluated using a range of 1,5-dihalopentanes. The concept of using 1-  
47  
48  
49 bromo-5-chloropentane was investigated as it was reasoned that less of this reagent  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 would be required due to the difference in reactivity between the two ends. However, it  
4  
5  
6  
7 was not possible to develop reproducible conditions using this approach, and the more  
8  
9  
10 standard 1,5-dibromopentane was employed. The reaction conditions and solvent were  
11  
12  
13  
14 evaluated using factorial experimental design, with the optimized conditions using  
15  
16  
17 potassium carbonate in MEK affording >98% conversion. The obtained crude material  
18  
19  
20  
21 was purified by flash column chromatography affording the product (**16**) with 98% Area  
22  
23  
24 HPLC purity.  
25  
26  
27

28 The half of the PBD dimer with the linker-payload trigger portion was prepared by  
29  
30  
31 coupling **3** with Alloc-Val-Ala-PAB-OH, using CDI as a safer, more convenient  
32  
33  
34 alternative to the standard phosgene conditions to afford the carbamate (**17**) in high  
35  
36  
37 yields. The TIPS-group was deprotected using lithium acetate/DMF and the resulting  
38  
39  
40  
41 phenol (**18**) was used without further purification. The two halves of the PBD-dimer  
42  
43  
44  
45 were then coupled together to afford the required bis-TBS ether (**10**). This reaction was  
46  
47  
48  
49 also optimized using factorial experimental design, with the best conditions utilizing  
50  
51  
52 potassium carbonate in MEK with the addition of tetrabutylammonium iodide (TBAI).  
53  
54  
55  
56 The reaction was slow, typically taking 4-5 days, but a conversion of >98% could be  
57  
58  
59  
60

1  
2  
3  
4 obtained and the resulting crude material was purified by flash column chromatography  
5  
6  
7 to afford **10** in good purity. Removal of the TBS-groups was achieved simply using  
8  
9  
10 TsOH in aqueous THF, and the resulting diol (**11**) could be obtained as solid following  
11  
12  
13 precipitation from methyl-THF and heptane. The oxidative cyclisation was then  
14  
15  
16 completed using the previously developed Stahl conditions and the product purified by  
17  
18  
19 reverse-phase HPLC to afford dimer (**12**). The final steps, common to the original route,  
20  
21  
22 involved alloc-deprotection and coupling of the PEG-maleimide linker, and these utilized  
23  
24  
25 conditions developed in previous campaigns, including purification using reverse-phase  
26  
27  
28 HPLC, to afford tesirine with 98.9% Area HPLC purity. The manufacturing campaign  
29  
30  
31 started with 1.3kg of intermediate **2**, and successfully delivered 151g of tesirine  
32  
33  
34  
35  
36  
37  
38 (Scheme 4).

58  
59  
60

With the new route having been demonstrated on a manufacturing scale, an analysis of the benefit of applying route design with a focus on reduction in the number of steps requiring high-containment was completed. A direct comparison of Cost of Goods (CoGs), utilizing \$/g for tesirine delivered, showed that the new route afforded material that was 40% of the cost of the original route. It is worth noting that although the number of high-containment steps has been minimized to 3 steps (Figure 2, total number of synthetic chemistry steps in the new route is 30), these steps still represent 50% of the overall cost of the campaign.

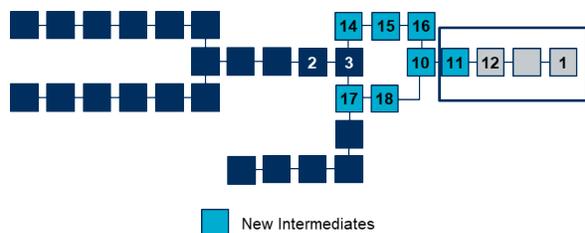

Figure 2. Schematic of revised synthesis of tesirine (each block representing an intermediate) showing portion conducted in high containment (inside blue box).

As noted previously, the concept of applying route design to minimize the number of steps requiring high-containment is applicable to the synthesis of all cytotoxic molecules. This concept is of significance for large-scale/commercial synthesis of cytotoxic molecules, but will be of interest to all chemists working on designing and developing improved routes to such molecules.

## Conclusions

In summary, a new approach to route design for the synthesis cytotoxic payloads has been presented which focusses on the reduction in the number of synthetic chemistry steps requiring high-containment facilities. This has been exemplified by the development of an improved synthesis of the ADC linker-payload tesirine, where reducing the number of high-containment steps from 8 to 3 has afforded a 60% reduction in CoGs. This approach has broader applicability to the synthesis of cytotoxic molecules and provides an important focus for the development of new and improved routes to molecules with commercial potential.

## Experimental Section

**General Procedures.** All solvents and reagents were commercially obtained and used without purification. Advanced intermediates were prepared using previously reported routes by dedicated Contract Manufacturing Organisations. NMR spectra were recorded on a Bruker 500MHz spectrometer. Accurate mass spectra analyses were recorded on a Waters LC-MS ZQ 2000 system in positive electrospray ionization mode (ESI).

*(S)*-(2-amino-5-methoxy-4-(triisopropylsilyloxy)phenyl)(2-((*tert*-butyldimethylsilyloxy)methyl)-4-methyl-2,3-dihydro-1H-pyrrol-1-yl)methanone (**3**).<sup>12</sup> To a solution of *(S)*-(2-((*tert*-butyldimethylsilyloxy)methyl)-4-methyl-2,3-dihydro-1H-pyrrol-1-yl)(5-methoxy-2-nitro-4-(triisopropylsilyloxy)phenyl)methanone (**2**, 237g, 97.8% w/w, 0.40mol) in EtOH (2400mL) was charged zinc dust (234g, 3.58mol, 8.95eq). A solution of ammonium acetate (285g, 3.60mol, 9.00eq) in water (360mL) was added at a rate to control the exotherm, maintaining the reaction between 15 and 30°C. When full conversion was achieved the mixture was filtered to remove the inorganic solids. The

1  
2  
3 residual solids were washed with EtOH (200ml) and the filtered washings added to the  
4  
5  
6  
7 filtered reaction solution. The solution was then concentrated, removing approximately  
8  
9  
10 1500mL of EtOH affording a two-phase mixture. EtOAc (2000mL) and water (1000mL)  
11  
12  
13 were added and the layers separated. The organic phase was washed with 6% w/w  
14  
15  
16  
17 aqueous sodium hydrogen carbonate solution. The combined aqueous phases were  
18  
19  
20  
21 extracted with EtOAc (1000mL) and the organic phases combined. The combined  
22  
23  
24 EtOAc layers were washed with water (2 × 1000mL) and 10% w/w aqueous sodium  
25  
26  
27  
28 chloride solution (2 × 1000mL) then the solvent was removed in vacuo affording the  
29

2  
3 (17.4g, 0.13mol, 0.52eq) was added. After a total reaction time of 118 hours, the  
4  
5  
6  
7 reaction was cooled and water (1500mL) added. The layers were separated and the  
8  
9  
10 organic layer washed with saturated aqueous sodium hydrogen carbonate solution  
11  
12  
13 (600mL) and saturated aqueous sodium chloride solution (300mL). The solvent was  
14  
15  
16 removed in vacuo and the residue dissolved in MTBE (1500mL) and washed with water  
17  
18  
19 (1000mL). The organic layer was filtered through a plug of silica gel (340g), eluting with  
20  
21  
22  
23  
24 MTBE (1800mL) and the solvent removed from the filtrate in vacuo affording a tan foam.  
25  
26  
27  
28 The material was dry-loaded onto silica gel (600g) using MTBE and purified in portions  
29  
30  
31 using flash column chromatography (80g of dry-loaded silica gel, 330g of silica gel,  
32  
33  
34 gradient of 45% to 100% EtOAc in petroleum ether). Impure fractions were collected  
35  
36  
37  
38 and further purified using the same procedure. The purified material was combined  
39  
40  
41

4  
5  
6  
7 methoxyphenyl}carbamoyl)oxy]methyl}phenyl)-L-alaninamide (**11**) (230g, 0.207mol) was  
8  
9  
10 dissolved in DCM (4600mL) at 23°C and the mixture sparged with air.  
11  
12  
13 Tetrakisacetonitrile copper(I) triflate (27.4g, 0.073mol, 0.35eq) and freshly prepared  
14  
15  
16  
17 TEMPO Stahl solution (363mL, 0.2M in MeCN, 0.072mol, 0.35eq) were added and the  
18  
19  
20 mixture stirred at ambient temperature with an air sparge for 24h. The reaction mixture  
21  
22  
23 was then washed with 5% w/v aqueous sodium thiosulfate solution (2300mL) and the  
24  
25  
26  
27 aqueous wash back extracted with DCM (1150mL). The combined organic portions  
28  
29  
30 were washed with saturated aqueous ammonium chloride solution (2 × 4600mL) and  
31  
32  
33  
34 1% aqueous sodium chloride solution (2 × 2070mL) and the solvent removed in vacuo.  
35  
36  
37  
38 The resulting crude material was dissolved in DCM (4600mL) and the solvent removed  
39  
40  
41 in vacuo three times, then the final crude material was dissolved in DCM (4830mL).  
42  
43  
44  
45 The solution was purified in portions using high pressure liquid chromatography (eluting  
46  
47  
48 with DCM/MeOH 95.5/4.5 (v/v)). The purified material was combined and the solvent  
49  
50  
51 removed in vacuo affording the product as a colourless oil. This oil was redissolved in  
52  
53  
54  
55 DCM to give the product (**12**, 4450g, w/w assay by HPLC 4.0%, assay corrected yield
