Oligomethylene-linked Bis-allenes Xin Tao,^a Karel Škoch,^a Constantin G. Daniliuc,^a Gerald Kehr,^a Gerhard Erker*^a

Borane-induced Ring Closure Reaction of

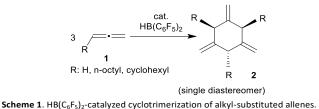

The trimethylene-linked bis-allene **3a** reacts with Piers' borane $[HB(C_6F_5)_2]$ by a hydroboration/allylboration sequence to generate the cyclization product **5a**. Its pyridine adduct was isolated and characterized by X-ray diffraction. Compound **5a** undergoes a typical frustrated Lewis pair 1,2-P/B alkene addition reaction with PPh₃ to give the heterobicyclic bridged olefinic zwitterionic product **9a**. The tetramethylene-linked bis-allene **3b** and its phenylene annulated analogue **3c** react with HB(C₆F₅)₂ to give the analogous seven-membered ring products **5b**,**c** under mild conditions. The cyclization product **5a** undergoes a series of sequential allylboration reactions with two equivalents of allene followed by ring-closure to give the four-component coupling product **12a**. It undergoes FLP addition to an exo-methylene group upon treatment with PPh₃. Compound **12a** is oxidatively converted to the boron-free alcohol.

Allenes are important building blocks in organic synthesis.¹ They show interesting and useful stereochemical properties.² We had recently shown that the borane $[HB(C_6F_5)_2]^3$ catalyses the cyclotrimerization of allene as well as a small series of mono-alkyl-substituted allenes **1** to selectively give the respective 1,3,5-trimethylene cyclohexanes **2** as single isomers under metal-free conditions (Scheme 1).^{1,4,5}

Scheme 1. HB(C₆F₅)₂-catalyzed cyclotrimerization of alkyl-substituted allenes.

There is a rich cyclization chemistry of bis-allenes reported in the literature (see Chart 1). Systems I (mostly with X = NTs, less frequently CR₂ or O) were reported to rearrange to II thermally induced.^{6a} They added R₃Si-SnBu₃/ or -GeR₃ reagents Pd(0) catalysed or radical induced to give the products III.^{6b,c} With H₂NR nucleophiles cyclization to medium-sized rings (e.q. IV) was reported.^{6d} The products V and VI of internal [2+2] cycloaddition were formed under the influence of Au(I)^{6e} or Pd(0)^{6a} catalysis, respectively. In some cases coupling between two bis-allenes occurred to give hetero-steroidal

frameworks.^{6f,g} It should be noted that the vast majority of these reaction is metal catalysed.

This posed the question what the favoured reaction pathway would be if we treated e.g. oligomethylene-linked bis-allenes with $HB(C_6F_5)_2$,⁷ i.e. under metal-free conditions. We have now performed these reactions starting from two examples of that bis-allene family. It turned out that a different cyclization type prevailed under these conditions. The outcome of these reactions will be presented and discussed below.

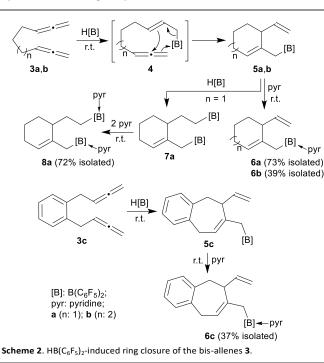

Results and discussion

Borane-induced ring-closure reaction of the bis-allenes

The allenes **3a** and **3b** (Scheme 2) were prepared by a variant of the Crabbé reaction as described by Ma et al.⁸ Copper (I) induced treatment of 1,6-heptadiyne with para-formaldehyde as C₁-building block and dicyclohexylamine gave the trimethylene-linked bis-allene **3a**^{6h} (40% isolated). The analogous reaction starting from 1,7-octadiyne gave the

tetramethylene-linked bis-allene **3b**⁶ⁱ (63% isolated, see the ESI for details). The phenylene containing bis-allene **3c** was synthesised analogously.

We reacted compound 3a with one molar equivalent of Piers' borane [HB(C₆F₅)₂]. The rapid reaction (r.t., minutes, in CD₂Cl₂) gave the cyclized product 5a. It was not isolated but characterized by spectroscopy [¹H NMR: δ 5.55 (olefinic =CH–) (C6-H, see Figure 1 for the unsystematic atom numbering scheme), δ 5.52, 5.03, -CH=CH₂ substituent); ¹¹B NMR: δ 69.3; $\Delta \delta^{19} F_{m,p}$ = 13.1 ppm]. Compound **5a** was then generated *in situ* on a preparative scale and trapped by subsequent addition of pyridine. We isolated the pyridine adduct 6a as a white crystalline solid in 73% yield. The X-ray crystal structure analysis of compound 6a showed the newly formed cyclohexene core that has a vinyl group attached in the allylic position and it bears the $-CH_2B(C_6F_5)_2(pyridine)$ substituent adjacent to it at the olefinic ring carbon atom C4 (Figure 1). In solution (CD₂Cl₂) we monitored the typical ¹H/¹³C NMR features of the vinyl group at carbon atom C3 and the central doubly substituted cyclohexene core. The ¹H NMR features of the coordinated pyridine moiety show up at δ 8.67, 8.11 and 7.65 (¹¹B: δ –0.6). Due to the chiral centre (ring carbon C3) the C_6F_5 groups at boron are diastereotopic and give rise to a 1:1 set of the respective o,p,m-C₆F₅ ¹⁹F NMR signals.

We assume that the reaction started with hydroboration of the terminal =CH₂ unit of one allenyl group by the HB(C₆F₅)₂ reagent. This resulted in the formation of the functionalized borane **4** which contained a reactive allylborane unit opposite to a reactive allene unit. This situation was set up for an internal allylboration reaction of the allene, which directly opened a pathway to the observed cyclization product **5a**. Addition of the pyridine Lewis base to the strongly Lewis acidic B(C₆F₅)₂ group gave **6a** (Scheme 2).

We reacted the tetramethylene-linked bis-allene $A\mathbf{b}_{e}$ with HB(C₆F₅)₂ and found that the seven-membered Correction product **5b** was formed analogously. Treatment of the *in situ* generated borane **5b** with pyridine gave the respective pyridine adduct **6b**, which we isolated crystalline in 39% yield. Compounds **5b** and **6b** were characterized by spectroscopy (see the ESI for details); product **6b** was characterized by C,H,N elemental analysis and by an X-ray crystal structure analysis (Figure 2). It shows the newly formed seven-membered ring in a typical cycloheptene boat-like conformation.⁹ The $-CH_2B(C_6F_5)_2$ moiety is attached at the sp²-carbon atom C4 (the boron atom bears a pair of C₆F₅ groups and the coordinated pyridine ligand in a pseudo-tetrahedral geometry). The vinyl substituent bonded to carbon atom C3.

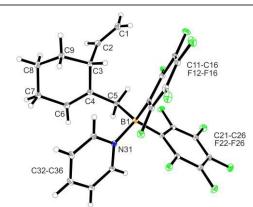

Figure 1. A view of the molecular structure of the borane pyridine adduct 6a. Selected bond lengths (Å) and angles (°): B1–N31 1.613(3), B1–C5 1.651(3), C1–C2 1.322(4), C4–C6 1.337(3), B1–C5–C4 117.7(2).

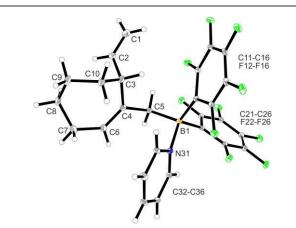

Figure 2. Molecular structure of compound 6b. Selected bond lengths (Å) and angles (°): B1–N31 1.627(5), B1–C5 1.645(6), C1–C2 1.285(8), C4–C6 1.340(6), B1–C5–C4 119.9(3).

The reaction of the bis-allene **3a** responded to the stoichiometry of the HB(C₆F₅)₂ reagent since the primary ringclosure product **5a** contained a reactive pendant vinyl group. Therefore, the reaction of **3a** with two molar equivalents of Piers' borane gave the bis-borane product **7a**. Its ¹¹B NMR spectrum showed two signals (δ 73.3 and δ 69.4) that are attributed to the pair of Lewis acidic planar-tricoordinate boron centres. Consequently, we observed two sets of ¹⁹F NMR resonances of the pairs of the C₆F₅ substituents at the two B(C₆F₅)₂ groups. The in situ generated bis-borane **7a** was then treated with two molar equivalents of pyridine to give the

respective double pyridine adduct **8a** (isolated as a white solid in 72% yield). It was characterized by C, H, N elemental analysis, by X-ray diffraction (the structure is shown in the ESI) and by spectroscopy. Due to the chiral centre (C3) the pair of C₆F₅ groups at each B(C₆F₅)₂(pyridine) moiety are diastereotopic and, consequently, we observed four sets of *o*,*m*,*p*-C₆F₅ ¹⁹F NMR signals of compound **8a**. We observed two sets of pyridine ¹H/¹³C NMR resonances and located the single olefinic ¹H NMR signal (C6-H) at δ 4.35 (t, J_{HH} = 3.3 Hz, 1H).

We performed the reaction of phenylene bridged bis-allene system **3c** in a similar way. The reaction of **3c** with one molar equiv. of HB(C₆F₅)₂ was carried out in CD₂Cl₂ at r.t. and the almost instantaneously *in situ* generated product was characterized by NMR spectroscopy [¹H: δ 5.48/5.13/5.08 (vinyl substituent), 5.72 (ring-CH=), ¹¹B: δ 71.7, ¹⁹F: $\Delta \delta^{19}$ F_{m,p}= 13.2]. The latter heteroatom NMR signals are typical for the presence of strongly Lewis acidic tricoordinate boron with this substituent pattern. Compound **5c** was treated with pyridine and the respective pyridine/borane Lewis adduct **6c** was isolated in 37% yield after workup involving pentane extraction. The NMR spectra now show a ¹¹B NMR resonance in the typical range of tetracoordinate boron (δ –0.5) and the C₆F₅ substituents at boron are diastereotopic (see the ESI for further details).

Subsequent FLP ring-closure reactions

The compounds **5** each contain a sterically encumbered, strongly Lewis acidic borane functionality and in its vicinity an accessible reactive vinyl group. We used this for carrying out a typical frustrated Lewis pair¹⁰ reaction, namely a 1,2-borane/phosphane addition to the C=C double bond.¹¹

We reacted the in situ generated cyclization product 5a with triphenylphosphane at room temperature. The reaction was practically instantaneous under these typical conditions and we isolated the P/B addition product 9a to the internal vinyl group as a white powder in 76% yield (Scheme 3). Single crystals of compound 9a that were suited for the X-ray crystal structure analysis were obtained at room temperature from a solution in dichloromethane that was layered with pentane. It showed that 1,2-phosphane/borane addition to the vinyl substituent had occurred. The internal -B(C₆F₅)₂ Lewis acid had been added to the =CH₂ terminus of the alkene and the external PPh₃ nucleophile to the -CH= carbon atom. The resulting zwitterionic heterobicyclo[4,4,0]decene type system features a bridgehead C=C double bond (C4–C6) and a borate system inside the heterocyclic six-membered ring that was formed in the FLP addition reaction. Consequently, the -PPh₃⁺ -phosphonium substituent is found attached at the same ring at carbon atom C2. We have isolated a single diastereoisomer of 9a from this reaction; it features the hydrogen atoms at carbon atoms C2 and C3 oriented trans to each other at the heterobicyclic framework (Figure 3). In solution compound 9a shows the NMR heteronuclear resonances at δ –12.3 (¹¹B) and δ 27.9 (³¹P). A diastereotopic pair of C₆F₅ substituents is bonded at boron, giving rise to two separate sets of ¹⁹F NMR resonances. The ¹H

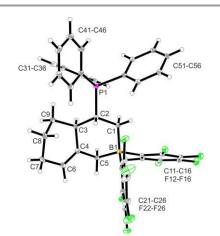

Figure 3. Molecular structure of the P/B FLP addition product **9a.** Selected bond lengths (Å) and angles (°): B1–C1 1.647(2), B1–C5 1.640(2), P1–C2 1.856(2), C1–C2 1.549(2), C4–C6 1.333(2), C1–B1–C5 105.7(1), B1–C1–C2 114.6(1), C1–C2–C3 112.4(1), C2–C3–C4 109.2(1), C3–C4–C5 114.9(1), C4–C5–B1 108.9(1), P1–C2–C1 109.3(1), P1–C2–C3 111.9(1), P1–C2–C3–C4 174.9(1), P1–C2–C1–B1 175.9(1).

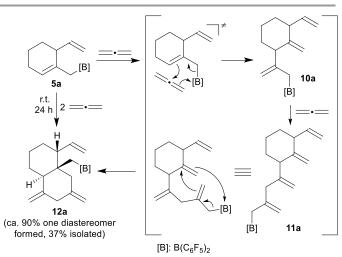

The seven-membered ring compounds **5b** and **5c** react analogously with PPh₃. Compound **5b** was in situ generated and triphenylphosphane was added. We isolated the product **9b** in 61% yield by crystallization. It was characterized by C, Helemental analysis, by spectroscopy and by X-ray diffraction. The molecular structure is similar to that of **9a**. It also contains a trans-relationship of the C3-H and C2-H hydrogen atoms of the heterobicyclic ring system. The hetero-NMR signals occur at δ -13.3 (¹¹B) and δ 30.5 (³¹P). Compound **9c** was prepared analogously from **5c** (see Scheme 3). It was isolated as a white solid in 77% yield after workup and characterized by NMR spectroscopy and by an X-ray crystal structure analysis. For further details of the characterization of the compounds **9b** and **9c** including their depicted molecular structures see the ESI.

Subsequent cyclooligomerization reaction with allene

Internal allene allylboration¹² represents the important step of the ring-closure reaction sequence starting from **3** to form the products **5**. The compounds **5** themselves each contain an allylborane functionality which might show the respective reactivity towards added allene reagents. Therefore, we exposed the cyclization product **5a** to an excess of the parent

ARTICLE

allene H₂C=C=CH₂. An NMR experiment revealed a close to complete conversion to the new product 12a within 24 h at room temperature. We carried out this reaction on a preparative scale under analogous conditions. Workup involving crystallization from pentane at -35 °C (3 d) gave the crystalline product 12a, which we isolated in 37% yield. Compound 12a was characterized by C, H elemental analysis, by spectroscopy and by an X-ray crystal structure analysis. This showed (Figure 4) that the endocyclic allylborane moiety of the starting material 5a had reacted with two molar equivalents of $H_2C=C=CH_2$ to give the functionalized decalin derivative **12a**. Apparently, compound **5a** had undergone an allylboration reaction with allene to generate the intermediate 10a. This itself represents an "elongated" allylborane system, that subsequently took up another allene equivalent to give 11a. The intermediate 11a could in principle have reacted with further allene, but instead its allylborane "found" the remaining exomethylene group at the six-membered core with which it underwent a favoured intramolecular allylboration reaction⁴ to directly give the observed product 12a (Scheme 4).

Scheme 4. Formation of compound 12a and allene by sequential allylboration reactions

Journal Name

consecutive C-C coupling between 5a and vitwoticle molar equivalents of allene. The ring carbon atom103/9868688786 remaining vinyl substituent; carbon atoms C10 and C12 are both part of the pair of exo-methylene groups 1,3-positioned in the second ring. The $-CH_2B(C_6F_5)_2$ group is attached at the bridgehead carbon (C4 in Figure 4).

In solution (CD₂Cl₂) compound 12a shows the typical NMR features of the vinyl substituent. The pair of =CH2 exomethylene groups shows a total of four ¹H NMR resonances (δ 4.85/4.61 and δ 4.68/4.42). The –CH₂[B] substituent shows the ¹H NMR signals of a pair of diastereotopic hydrogen atoms (AB system at δ 2.30/2.15; ¹³C: δ 36.7). The corresponding ¹¹B NMR feature is at δ 76.4, i.e. in a typical range of a strongly Lewis acidic tri-coordinated boron atom in this substituent situation.¹³ Consequently, we observed three ¹⁹F NMR signals of the pair of the C₆F₅ substituents at boron with a large $\Delta \delta^{19}$ F_{m,p} = 11.5 ppm chemical shift separation.

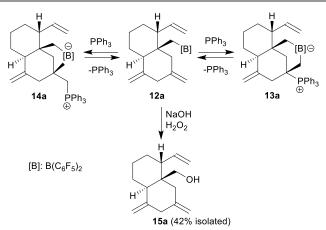

Some typical reactions of the borane 12a

Compound 12a is a reactive borane and it contains C=C double bond functionalities. Therefore, it should be suitable to undergo typical FLP addition to one of the olefinic units in the presence of an external phosphane nucleophile.¹¹ We, consequently, reacted the in situ generated borane 12a with triphenylphosphane in dichloromethane. The reaction with PPh₃ was instantaneous. The volatiles were removed and the residue was washed with pentane to give the P/B addition product 13a, which we isolated as a white solid in 56% yield (see Scheme 5). Compound 13a was characterized by C, H-elemental analysis, by spectroscopy and by X-ray diffraction (Figure 5). It showed that a P/B FLP addition had taken place at the proximal C=CH₂ moiety (C12=C15 in compound **12a**, see Figure 4) by using the adjacent pendent internal borane and the external phosphane. Compound **13a** is the isomer that was formed by borane addition to the C=CH₂ terminus and, consequently, phosphane addition to the sp²-ring carbon atom. This resulted in the formation of a heterocyclic six-membered ring-system that had become 1,3-attached at the "lower" six-membered decalin ring of compound 12a. The phosphonium PPh₃⁺ moiety is found attached at the new bridgehead atom C12 (Figure 5).

Compound **13a** shows a typical borate ^{11}B NMR resonance at δ –15.1 in solution (CD₂Cl₂, 273 K) and a phosphonium ^{31}P NMR signal at δ 31.1. It shows the ^{19}F NMR features of a pair of diastereotopic C₆F₅ groups at the boron atom (for further details of the NMR characterization of compound **13a** see the ESI).

Compound **13a** is the P/B FLP addition product that is formed under kinetic control. When we stored the CD₂Cl₂ solution of compound **13a** for 7 days at room temperature the resulting NMR spectra showed the formation of an equilibrium mixture of **13a** (ca. 20 mol%), the starting material **12a** (plus PPh₃, ca. 8 mol%) and the new compound **14a** (65 mol%) (plus some minor contaminants). The major product **14a**, apparently formed under thermodynamic control, was prepared similarly on a preparative scale (24 h, r.t., CH₂Cl₂ layered with pentane) and crystallized from the mixture. Crystalline compound **14a** was isolated in 60% yield and the product was characterized by C, Helemental analysis, by spectroscopy and by X-ray diffraction.

Scheme 5. Reaction of compound 12a with PPh_3 and oxidative replacement of the boryl group.

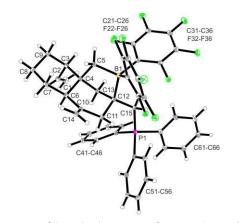

Figure 6. A projection of the molecular structure of compound 14a. Selected bond lengths (Å) and angles (*): B1–C5 1.657(4), B1–C12 1.695(3), P1–C15 1.823(2), C1–C2 1.301(13), C4–C6 1.556(3), C10–C14 1.325(4), C12–C15 1.540(3), C5–B1–C12 99.9(2), C12–C15–B1 112.1(2), B1–C12–C15–P1 179.1(2).

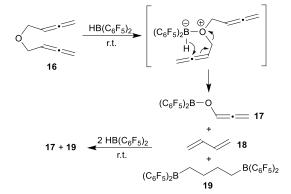

The X-ray crystal structure analysis of **14a** shows the presence of five-membered boratacycle that is **1**,3-annulated to the "lower" six-membered ring of the *trans*-decalin framework. It was apparently formed by a **1**,2-P/B FLP addition to the C12=C15 carbon-carbon double bond of the starting material

12a, similar as we had seen it in the formation of its isomer **13a**, only that in this case PPh₃ addition had taken¹ β is a second the second terminus of the exo-methylene group concurrent with borane addition to its adjacent doubly substituted sp²-carbon atom. The structure of the resulting P/B zwitterion **14a** is depicted in Figure 6.

The ¹H NMR spectrum of compound **14a** (in CD₂Cl₂, at 299 K) shows the P-coupled system of the exocyclic $-CH_2-[P]$ moiety at δ 4.18/2.70 and the resonances of the endocyclic $-CH_2-[B]$ group at δ 1.32/0.35. The heteroatom NMR signals occur at δ -6.8 (¹¹B) and 19.9 (³¹P), respectively and we observed two sets of ¹⁹F NMR signals of the pair of diastereotopic C₆F₅ groups at boron (for further details see the ESI).

We eventually converted the borane-induced multi-component cyclization product **12a** to a boron-free derivative.¹⁴ This was carried out in the usual way of oxidative deborylation as it is done in the conventional hydroboration chemistry.¹⁵ Treatment of the strongly electrophilic $-B(C_6F_5)_2$ borane **12a** with NaOH/H₂O₂ gave the alcohol **15a** that we isolated as a white solid in 42% yield after workup (see the ESI for its characterization by NMR spectroscopy).

We briefly investigated the reaction of the bis-allenic ether 16^{6c,h,j} with HB(C₆F₅)₂. The reaction was carried out in CD_2Cl_2 solution at r.t. The products of the reaction were not isolated but directly identified in situ generated from the solution. We subsequently added a total of three molar equivalents of HB(C₆F₅) to eventually achieve a complete conversion of compound 16 with a clean product formation. The NMR analysis (for details see the ESI) revealed that the by far predominant reaction was ether cleavage. This gave the (C₆F₅)₂B-O-CH₂-CH=C=CH₂ cleavage product 17 (see Scheme 6) and butadiene (18) as primary products. The latter was then subsequently converted by added HB(C_6F_5)₂ to the bis-hydroboration product 19. The boryl ether 17 also was not stable under the reaction conditions, probably due to subsequent ether cleavage with additional HB(C₆F₅)₂ (see the ESI for details). We also investigated briefly the reaction of the respective bis-allenic Ntosyl amine with HB(C₆F₅)₂, but that gave a complicated mixture of as yet unidentified products.

Scheme 6. Reaction of the bis-allenic ether 16 with HB(C₆F₅)₂.

Conclusions

With this study we have found a new variant of our borane induced carbon-carbon coupling reactions between allene building blocks. In this case the reaction starts as it is commonly observed in our systems by 1,2-[B]-H addition¹⁶ to a terminal allene = CH_2 group by the strongly electrophilic HB(C₆F₅)₂ hydroboration reagent to probably generate a reactive allylborane intermediate in situ, which is set for undergoing rapid intramolecular ring-closure with the pendant second allenyl moiety to generate the products 5a to 5c, respectively. These are then obviously protected by their special geometry from undergoing further intermolecular allylborane coupling under the applied reaction conditions, so that the reaction stopped at the functionalized six-or seven-membered ring products. The compounds 5 are, however, in principle still active allylboration reagents. This we could show by the rapid reaction of the example **5a** with the parent allene $H_2C=C=CH_2$. Two equivalents of allene were consumed in a sequence of consecutive intramolecular allylboration reactions, followed by a final intramolecular allylboration ring-closure reaction to give the four-component coupling product 12a. This in turn was oxidatively converted to the boron-free product 15a. These metal-free reactions are markedly different from the common metal catalysed bis-allenic cyclization reactions reported in the literature (see Chart 1 and the respective references). We will see how the products of our metal free cyclization reactions and their follow-up products (and related systems) might become easily available useful reagents for further external C-C coupling reactions using either of the newly generated functionalities.
