# Controllable Isomerization of Alkenes by Dual Visible-Light-Cobalt Catalysis

#### Qing-Yuan Meng, Tobias E. Schirmer, Kousuke Katou and Burkhard König\*

**Abstract:** We report here that thermodynamic and kinetic isomerization of alkenes can be accomplished by the combination of visible light with Co catalysis. Utilizing Xantphos as the ligand, the most stable isomers are obtained, while isomerizing terminal alkenes over one position can be selectively controlled by using DPEphos as the ligand. The presence of the donor-acceptor dye 4CzIPN accelerates the reaction further. Transformation of exocyclic alkenes into the corresponding endocyclic products could be efficiently realized by using 4CzIPN and Co(acac)<sub>2</sub> in the absence of any additional ligands. Spectroscopic and spectroelectrochemical investigations indicate Co<sup>1</sup> being involved in the generation of a Co hydride, which subsequently adds to alkenes initiating the isomerization.

Isomerization of alkenes is a straightforward and atomeconomic approach to the synthesis of desired isomers, some of which are not easily accessible by conventional methods.<sup>[1]</sup> Over the past decade, tremendous efforts have been dedicated to the development of strategies based on noble metal complexes including Ru,<sup>[2]</sup> Rh,<sup>[3]</sup> Pd<sup>[4]</sup> and Ir,<sup>[5]</sup> affording the isomerization of alkenes over one position. Comparatively, the use of non-noble metals<sup>[6]</sup> especially Co in combination with appropriate ligands as catalysts enables this transformation at lower cost. For example, Holland and Weix<sup>[6d]</sup> applied a β-diketiminate Co<sup>II</sup> complex to catalyze the isomerization of terminal alkenes to 2alkenes with high Z stereochemistry and Shenvi<sup>[6e]</sup> achieved the isomerization of terminal alkenes as well as the subsequent cycloisomerization by using Co(Sal<sup>t</sup>Bu,<sup>t</sup>Bu)Cl as catalyst. Liu and Jiao<sup>[6h]</sup> reported a kinetically controlled regioselective olefin isomerization reaction catalyzed by a Co complex with a NNPpincer ligand. Recently, Schoenebeck and coworkers<sup>[6]</sup> developed an additive-free system for the isomerization of alkenes using a [Ni(µ-Cl)IPr]2 dimer as an effective catalyst (Scheme 1a). Although significant advances have been achieved, a controllable and simple regio- and stereo-selective isomerization of alkenes is still challenging and appealing.

The renaissance of visible light photocatalysis over the last decade provides in many cases a milder approach to organic synthesis. A classic photocatalytic transformation is the *E*/*Z* isomerization of alkenes, which can be accomplished efficiently by photosensitized triplet energy transfer (Scheme 1b).<sup>[7]</sup> However, translocation of alkenes over one carbon or more by visible light photocatalysis is rarely reported. Lanterna and Scaiano disclosed the photochemical isomerization of alkenes

over one carbon using Pd-decorated TiO<sub>2</sub> as the photocatalyst, and very recently Shionoya established PdCl<sub>2</sub> centers on the inner surfaces of a metal-macrocycle framework (MMF) for photochemical alkene migration, but only benzyl-substituted alkenes were presented (Scheme 1c).<sup>[8]</sup> We report here the combination of visible light catalysis with Co catalysis as a versatile protocol for the isomerization of alkenes. The activity of the generated Co hydride intermediates can be effectively controlled by ligands, thus allowing the isomerization of alkenes with high regio- and stereo-selectivity (Scheme 1d).

This work:

(d) Controllable isomerization of alkenes by visible light catalysis

We commenced our study of allylbenzene isomerization by using Co(acac)<sub>2</sub> and Xantphos as catalyst and ligand, respectively, and 2,6-dimethyl(2H)pyridine diethyl dicarboxylate (Hantzsch ester, HEH) was chosen as the reductant. Gratifyingly, a 77% yield of E-β-methylstyrene accompanied with small amounts of Z-β-methylstyrene and the hydrogenation product were obtained by irradiating the system with blue LEDs in CH<sub>3</sub>OH (Table 1, entry 1). Screening of solvents showed that the catalytic performance could be further improved in DMF, affording the desired isomer in 93% yield with high E/Z selectivity (Table 1, entries 2-9). Control experiments confirmed the essential role of the Co catalyst, the reductant HEH and irradiation (Table 1, entries 10-12). Interestingly, replacement of Xantphos with the donor-acceptor dye 2,4,5,6-tetra(carbazol-9yl)isophthalonitrile (4CzIPN) also gave an excellent transformation (Table 1, entry 13).

Having established the optimized reaction conditions, the scope for isomerizing alkenes into thermodynamically stable isomers was examined. All the allylbenzene derivatives underwent isomerization with good functional tolerance, generating the more stable *trans*-isomer in high yields ranging from 84 to 95% (Table 2, entries 2-5). Increasing the length of

the carbon chain by one compared to allylbenzene has virtually no impact on the yield and the stereoselectivity (Table 2, entries 6-10). However, further prolonging the carbon chain led to diminished reactivity and various isomers were obtained. We were pleased to find that isomerization of terminal alkenes proceeded efficiently when 4CzIPN was added, giving rise to the desired products in good yields (Table 2, entries 11 and 12). Presence of a second phenyl group at the benzylic position decreased the yield sharply for the Co Xantphos system, which may be caused by an increased steric hindrance. Using 4CzIPN instead of Xantphos resulted in an excellent transformation (Table 2, entry 13). Particularly, the branched alkene can be also converted into the conjugated product by isomerizing it over two positions (Table 2, entry 14).

[a] Unless otherwise noted, all the reactions were carried out with allylbenzene (0.2 mmol), Co(acac)<sub>2</sub> (0.01 mmol), Xantphos (0.02 mmol), HEH (0.2 mmol) and K<sub>2</sub>CO<sub>3</sub> (0.2 mmol) in the corresponding solvent (2 mL) under N<sub>2</sub>, irradiation with blue LEDs at 25°C for 16 hours. [b] Conversion (Conv.) and yield were determined by GC-FID, using 1,3,5-trimethoxybenzene as an internal standard. [c] Co(acac)<sub>2</sub> was not added. [d] HEH was not added. [e] The reaction was carried out in the dark. [f] Xantphos was replaced by 4CzIPN. [g] Xantphos was not added. HEH: Hantzsch ester. Xantphos: 4,5-bis(diphenylphosphino)-9,9-dimethylxanthene. 4CzIPN: 2,4,5,6-tetra(carbazol-9-yl)isophthalonitrile.

We next turned our interest to control the isomerization of alkenes over one position. 4-Ph-1-butene 1b was selected as the substrate and a variety of phosphine ligands were screened. To our delight, isomerization over one carbon can be controlled employing triphenylphosphine (PPh₃) bv or 1.4-bis-(diphenylphosphino)butane (dppb) as the ligand, albeit the yield and stereoselectivity are low (Table 3, entries 2 and 7). bis[(2-diphenylphosphino)phenyl] ether Amazingly, using (DPEphos) avoids further isomerization to the most stable conjugated isomer in an excellent way, affording the less stable isomer 1-Ph-2-butene 4b in 90% yield with aood stereoselectivity (E/Z = 80/20) (Table 3, entry 8). Other ligands

[a] Unless otherwise noted, all the reactions were carried out with alkenes (0.2 mmol),  $Co(acac)_2$  (0.01 mmol), Xantphos (0.02 mmol), HEH (0.2 mmol) and  $K_2CO_3$  (0.2 mmol) in anhydrous DMF (2 mL), irradiation with blue LEDs at 25 °C for 16 hours. [b] Isolated yields. [c] The ratio of *E/Z* was determined by <sup>1</sup>H NMR. [d] GC-FID yields using 1,3,5-trimethoxybenzene as an internal standard. [e] The reaction was carried out for 24 hours. [f] 4CzIPN (1 mol%) was added. [g] Xantphos was not used.

provided much lower conversions (Table 3, entries 3-6 and 9). Apparently, the amount of HEH could be decreased, but at the expense of lower stereoselectivity (Table 3, entries 10 and 11).

Having identified DPEphos as the optimal ligand, we compared the isomerization of 4-Ph-1-butene 1b with other known catalysts to demonstrate the advantage of our catalytic system for this alkene isomerization reaction (Table S1). Then we explored the generality of this regioselective isomerization and monitored the kinetic of reactions of 4-Ph-1-butene 1b (see discussion in Figure S1). The developed protocol was compatible with a variety of functional groups including fluoro, chloro, bromo and ester substituents, the product of which can be handled for further functionalization (Table 4, entries 2-7). Particularly, increasing the length of the carbon chain has only a minor influence on the outcome, giving rise to the corresponding products in good yields and stereoselectivity (Table 4, entries 8 and 9). Using 1,1-diphenyl derivatives as the starting materials, no overisomerization into the conjugated position was observed (Table 4, entry 10). It is important that condensed arenes and

electron-rich or -deficient heterocycles are tolerated by the reaction (Table 4, entries 11-13). Our catalytic protocol is also applicable to the isomerization of 1-octene and 1-octadecene, both of which proceeded in high levels (Table 4, entries 14 and 15). Interestingly, 1,1-disubstituted alkenes exhibited moderate reactivity when DPEphos was substituted by Xantphos and 4CzIPN (Table 4, entry 16). Furthermore, the flavoring agent D,L-limonene was used as the starting material, with no conversion achieved. Again, replacement of DPEphos with 4CzIPN was found to be beneficial for the reaction, producing terpinolene in a preparative yield (Table 4, entry 17).

[a] Unless otherwise noted, all the reactions were carried out with 4-phenyl-1-butene (0.2 mmol), Co(acac)<sub>2</sub> (0.01 mmol), ligand (0.02 mmol), HEH (0.2 mmol) and K<sub>2</sub>CO<sub>3</sub> (0.2 mmol) in DMF (2 mL) under N<sub>2</sub>, irradiation with blue LEDs at 25 °C for 16 hours. [b] GC-FID yield using 1,3,5-trimethoxybenzene as an internal standard. [c] The ratio of *E*/*Z* was determined by <sup>1</sup>H NMR. [d] 0.1 mmol HEH was used. [e] 0.04 mmol HEH was used.

The isomerization of exocyclic alkenes was also examined. We tried Xantphos and DPEphos in combination with the Co catalyst, giving almost no conversion. Delightfully, replacing of Xantphos and DPEphos by 4CzIPN enabled this kind of transformation to proceed very well (Table 5). One important constituent of pine resin (-)- $\beta$ -pinene was converted into (-)- $\alpha$ -pinene in a quantitative yield (Table 5, entry 3). Furthermore, we applied this protocol to isomerize one cholesterol derivative and the reaction also proceeded smoothly to give 96% yield of the final product with a ratio of 3:1 (Table 5, entry 4). Finally, isomerization of the remote exocyclic C-C double bond was evaluated and the endocyclic alkene was

[a] Unless otherwise noted, all the reactions were carried out with alkenes (0.2 mmol),  $Co(acac)_2$  (0.01 mmol), DPEphos (0.02 mmol), HEH (0.2 mmol) and  $K_2CO_3$  (0.2 mmol) in anhydrous DMF (2 mL), irradiation with blue LEDs at 25°C for 16 hours. [b] Isolated yields. [c] The ratio of *E/Z* was determined by <sup>1</sup>H NMR. [d] The reaction was carried out for 10 hours. [e] GC-FID yields using 1,3,5-trimethoxybenzene as an internal standard. [f] DPEphos was replaced by 4CzIPN (0.002 mmol) and Xantphos (0.02 mmol), irradiating for 24 hours. [g] 0.005 mmol of Co(acac)\_2 was used and DPEphos was replaced by 4CzIPN (0.002 mmol), irradiating for 24 hours.

obtained in a good yield (Table 5, entry 5). We compared our method with other catalysts known for the isomerization of (-)- $\beta$ -pinene. Only the Co(Sal<sup>t</sup>Bu,<sup>t</sup>Bu)Cl system showed similar reactivity, while other cases gave no or much lower yield of (-)- $\alpha$ -pinene. Therefore, our method provides a avaluable alternative to the Co(Sal<sup>t</sup>Bu,<sup>t</sup>Bu)Cl system by using visible light catalysis, whilst being ligand-free.

We employed spectroelectrochemistry and on-line irradiation to gain further insights of the reaction pathway. To avoid any effects by the insoluble base  $K_2CO_3$ , it was replaced by 1,8diazabicyclo[5.4.0]undec-7-ene (DBU) which also showed good performance in the reactions (Scheme S1). Spectroelectrochemistry revealed a new absorption between 450 and 600 nm with decreasing potentials, which can be attributed to one-electron-reduced Co(acac)<sub>2</sub> species (Figure

5

#### WILEY-VCH

S2a).<sup>[9]</sup> Introduction of DPEphos or Xantphos as ligand into the system enhanced the intensity of this absorption, indicating that Col can coordinate to DPEphos or Xantphos, whereas Coll showed no interaction as no change of absorption was observed when Co(acac)<sub>2</sub> and DPEphos or Co(acac)<sub>2</sub> and Xantphos were mixed (Figure S2b and S2c, Figure S3a and S3b), On-line irradiation experiments in the absence or presence of 4CzIPN showed a characteristic absorption in the same region by using HEH and DBU as the reductant and base, respectively. The observation supports the conclusion that Co<sup>I</sup> is involved in the catalytic system (Figure S2d and S3c, Figure S3d and S3e). Radical inhibiting experiments excluded the possibility of carboncentered radical species in our reaction (Scheme S2).<sup>[10]</sup> And results from mercury poisoning experiments indicate the homogeneous nature of the reaction (Scheme S3).[11]

Based on the above results, a plausible reaction pathway is proposed, shown in Scheme 2. Upon irradiation with visible light, photoexcited \*4CzIPN accepts one electron from HEH to afford 4CzIPN<sup>•</sup>, which can reduce Co<sup>II</sup> to Co<sup>I, [12]</sup> At high concentrations HEH shows absorption in the visible light region. We can therefore not exclude a direct reduction of Coll to Col by photoexcited HEH.<sup>[13]</sup> The so formed Co<sup>I</sup> coordinates to a phosphine ligand yielding the intermediate H-Co<sup>III</sup>L A after proton reduction.<sup>[14]</sup> Addition of A into a C-C double bond proceeds in Markovnikov orientation, giving rise to the alkyl Co<sup>III</sup> intermediate B. Considering that the reaction needs constant irradiation (Figure S4) and catalytic amounts of HEH can accomplish the reaction (Table 3, entries 10 and 11), the following β-hydride elimination could be promoted by photo irradiation,<sup>[15]</sup> leading to the product isomerized over one position. This isomerization is selective, if DPEphos was used as the ligand, while Xantphos promoted the subsequent addition of the Co hydride to the isomerized product (Figure S1d), which may be rationalized by its larger bite angle,<sup>[16]</sup> thus giving rise to higher reactivity of H-Co<sup>III</sup>L for the generation of the alkyl Co<sup>III</sup> intermediate **C**. Finally, β-hydride elimination proceeds smoothly again under irradiation, providing the stable conjugated product and regenerating A to finish the catalytic cycle.

Scheme 2. Plausible reaction mechanism

In conclusion, we have developed a mild approach to isomerize terminal alkenes. The method tolerates many functional groups and combines visible light catalysis and Co Regioselectivity and stereoselectivity of catalysis. the isomerization can be controlled by using Xantphos or DPEphos as ligand. Using additionally 4CzIPN as photosensitizer accelerates both reactions. Exocyclic alkenes were converted into endocyclic products in high efficiencies in the presence of the photo- and the Co catalyst, but without the use of any ligand. We believe this visible light-mediated translocation of alkenes provides a useful approach for the synthesis of alkene isomers for subsequent functionalization.

#### COMMUNICATION

A mild and highly efficient translocation of alkenes by dual visible-light-cobalt catalysis has been developed. By the proper choice of ligands, isomerization over one position or more than one position with tolerance of a variety of functional groups can be selectively achieved.
