Thioallenes, RSC(X)—C—CH₂ (R = CH₃, C₂H₅, Ph; X = OCH₃, H) react with Fe₃(CO)₁₂ to give products of type A. An additional product, B, is obtained when the thioallene used is PhSCH—C—CH₂. A complex

of this type and the isomer in which the RS groups are in trans position also are obtained in low yield in the case of CH₃SCH—C—CH₂, in addition to the type B major product. The formation of $(\mu$ -RS)₂Fe₂(CO)₆ as by-products indicates that some C-S bond cleavage occurs as well. The structures of one example each of structural types A and B have been determined: $(\eta^1:\eta^3$ -CH₃SCHCCH₂)Fe₂(CO)₆ (2a) for R = CH₃, X = H; $(\eta^3$ -PhSCHCCH₂)₂Fe₂(CO)₆ (15b) for R = Ph. Compound 2a crystallizes in the monoclinic space group $P2_1/c$ with a = 7.7134 (4) Å, b = 13.6321 (5) Å, c = 12.9757 (9) Å, $\beta = 102.318$ (6)°, V = 1333.0 (3) Å³, and Z = 4, and has refined to R = 0.041 and $R_w = 0.047$ based on 2192 unique observations. Compound 15b crystallizes in the triclinic space group $P\overline{1}$ with a = 10.938 (1) Å, b = 12.064 (2) Å, c = 9.806 (1) Å, c = 92.02 (1)°, c = 93.03 (1)°; c = 68.15 (1)°, c = 1199.2 (4) Å³, c = 2, and has refined to c = 0.038 and c = 0.054 based on 3360 unique observations.

Introduction

The thermal reaction of vinyl sulfides, RSCH=CH₂, with triiron dodecacarbonyl was reported to give low yields of $(\mu-\eta^1:\eta^2-CH_2=CH)(\mu-RS)Fe_2(CO)_6$ complexes.¹ A similar reaction between allenyl sulfides, RSC(R')=C=CH₂, might then be expected to result in formation of analogous $(\mu-\eta^1:\eta^2-\text{allenyl})(\mu-RS)Fe_2(CO)_6$ complexes, 1. We had

prepared complexes of type 1 in earlier studies by reaction of $[Et_3NH][(\mu\text{-CO})(\mu\text{-RS})Fe_2(CO)_6]$ with propargyl halides, $RC = CCH_2X$ (R = H, CH₃), ^{2a} and by the reaction of allenylmercuric iodide with $[Et_3NH][(\mu\text{-CO})(\mu\text{-RS})Fe_2-(CO)_6]$. An alternate route to such complexes would be of interest, and accordingly we have studied some reactions

of Fe₃(CO)₁₂ with various thioallenes. In part, these reactions took a different course than we had anticipated, one not involving C-S bond cleavage.

Results and Discussion

The initial reaction studied was that of 1-methoxy-1-(methylthio)allene, $(CH_3O)(CH_3S)C$ —C— CH_2 , with triiron dodecacarbonyl. A reflux period of 4 h under nitrogen in tetrahydrofuran (THF) solution was sufficient to cause a color change from the initial green of the Fe₃(CO)₁₂ to dark red. Two crystalline products could be isolated. One, a red-orange solid, was identified as a mixture of the two isomers of the known³ (µ-CH₃S)₂Fe₂(CO)₆. Its yield was 19%, based on available CH₃S groups, and its formation indicated that some C-S bond cleavage had indeed occurred. The other product, isolated in 48% yield, a redorange solid, was not the expected $(\mu - \eta^1) = -C(OCH_3)$ C=CH₂)(μ-CH₃S)Fe₂(CO)₆ since, according to its ¹H NMR spectrum, it did not contain a µ-CH₃S ligand, although its C, H analysis and EI mass spectrum suggested the presence of the CH₂CHC(OCH₃) and CH₃S groups as well as $Fe_2(CO)_6$.

Similar products were obtained on reaction of $(CH_3-O)(C_2H_5S)C=C=CH_2$ with $Fe_3(CO)_{12}$: $(\mu-C_2H_5S)_2Fe_2(CO)_6$

in 42% yield and a red, crystalline solid (also in 42% yield) that analyzed correctly for [(CH₃O)(C₂H₅S)(C₂CH₂)]Fe₂-(CO)₆. With (CH₃O)(t-BuS)C=C=CH₂, however, only $(\mu-t-BuS)_2Fe_2(CO)_6$ could be isolated in 74% yield.

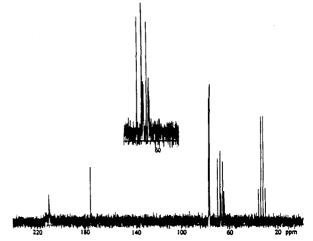

Reactions of Fe₃(CO)₁₂ with allenes of type RSCH= C=CH₂ also were studied. With CH₃SCH=C=CH₂, (μ-CH₃S)₂Fe₂(CO)₆ was obtained in 5% yield. A red compound of composition (CH₃SCHCCH₂)Fe₂(CO)₆ was the major (43%) product, but there was another minor orange-red product that, on the basis of its C, H analysis and FD mass spectrum, contained two units of the allene and one of Fe₂(CO)₆. In the case of the PhSCH=C= CH₂/Fe₃(CO)₁₂ reaction such a (PhSCHCCH₂)₂Fe₂(CO)₆ product was formed in higher (29%) yield in addition to the (PhSCHCCH₂)Fe₂(CO)₆ product (also in 29% yield). In marked contrast, C₂H₅SCH—C—CH₂ reacted with Fe₃(CO)₁₂ in refluxing THF to give mainly (93% yield) $(\mu-C_2H_5S)_2Fe_2(CO)_6$ and the $(C_2H_5SCHCCH_2)Fe_2(CO)_6$ product in only 5% yield.

The structure of the (C₄H₆S)Fe₂(CO)₆ product from the CH₃SCH=C=CH₂/Fe₃(CO)₁₂ reaction was determined by single-crystal X-ray diffraction and is represented in formula 2a. Figure 1 shows an ORTEP plot of the molecule,

and relevant bond lengths and angles are given in Tables I and II. Compound 2a contains an $\eta^1:\eta^3$ -bridging allyl ligand which is composed of the atoms C(1), C(2), and C(3), with C(2) being the central allyl carbon atom. Coordination of the methylthio group to iron closes a four-membered ring whose vertices are defined by Fe(1)-C(2)-C-(1)-S. The Fe(1)-Fe(2) bond length of 2.6177 (9) A is

within the typical range for an Fe-Fe single bond. The nearly identical C(1)–C(2) and C(2)–C(3) bond distances (1.401 (6) and 1.393 (6) Å, respectively), which are within the range for a C-C allylic bond, indicate that there is complete delocalization of the allyl group. The allyl carbon atom, C(2), is positioned equidistant from each iron center, Fe(1)-C(2) = 1.948 (4) Å, Fe(2)-C(2) = 1.953 (4) Å. The allyl ligand has a bond angle of 119.4 (4)° which is in close agreement with the 120° bond angle expected for an allyl group. The bond distance Fe(2)-C(1) of 2.078 (4) Å is shorter than its counterpart, Fe(2)-C(3), which is 2.174 (5) A. This is undoubtedly due to the strain imposed on the molecule by the sulfur atom which bridges C(1) and Fe(1).

Di- and trinuclear complexes with bridging allenyl ligands have been reported previously by others and three modes of bridging allenyl coordination are known: μ - η^2 : η^2 , C, as in 3⁴ and 4, μ - η^1 : η^3 , with a metal-metal bond, D, as in 5,6 and its ruthenium and osmium analogs,5,7 as well as

in 6^8 and $7;^9 \mu - \eta^1 : \eta^3$, without a metal-metal bond, E, as in 8^5 and 9^9 (Chart I).

Direct comparison of 2a can be made to other $(\eta^1:\eta^3$ -allyl)iron carbonyl complexes. Complex 5 is an oil, but a triphenylphosphine substitution product, 10, could be

prepared and its molecular structure was determined by Davis.¹⁰ The similarity of bond distances is striking. Distances equivalent to those in Figure 3 were as follows (in Å): Fe(1)-Fe(1), 2.65; C(1)-C(2), 1.45 (2); C(2)-C(3),

(10) Davis, R. E. Chem. Commun. 1968, 248.

Table III. ¹H NMR Spectrum (ppm) of 2a

| 2.48 (s, 3 H, CH ₃ S) | $4.08 (s, 1 H, = CH_2)$ |
|------------------------------------|----------------------------------|
| 3.32 (s, 1 H, CH ₃ SCH) | $4.20 \text{ (s, 1 H, } = CH_2)$ |

1.41 (2); Fe(1)–C(2), 2.03; Fe(2)–C(2), 1.93; Fe(2)–C(1), 2.18; Fe(2)–C(3), 2.19, with a C(1)–C(2)–C(3) angle of 116.0 \pm 1.3°. As in 2c, the Fe(1)–C(2) bond does not lie in the C(1)–C(2)–C(3) plane as a result of the constraint placed on the system by the presence of the short Fe–Fe bond.

Further examples are known of complexes in which a $\text{Fe}_2(\text{CO})_6$ unit is bridged by an η^1, η^3 -allyl ligand. Complex 11 is nearly identical to 5 except for the large poly-

$$F = C \qquad \qquad C \qquad P(C_{\theta}H_{11}\text{-cyclo})_{2}$$

$$(OC)_{3}Fe \qquad \qquad 12$$

$$11$$

methylene chain joining the two ends of the allyl group.¹¹ The bond distances and the internal angle of the allyl unit compare very closely with those reported for 10. More closely related to 2a is complex 12.12 As with 11, the allyl unit of 12 is part of a ring. However, here the ring is much smaller, only five-membered, and is substituted with fluorine atoms. The feature which bears a striking resemblance to 2a is the phosphine ligand which bridges C and the σ -bonded Fe(CO)₃ center to close a four-membered chelate ring. The σ -Fe-allyl carbon bond [Fe(2)-C(2) = 1.938 (5) Å] more closely resembles that of 2a [1.948 (4) Å] than that of either 10 (2.03 Å) or 11 (2.02 Å). This suggests that the iron-coordinated thio or phosphino group has some effect on the shortening of this bond. The C-(2)-C(3) bond distance of 1.393 (7) A is significantly shorter than C(1)-C(2) at 1.447 (7) Å, which implies that C(2)-C(3) has more double bond character and that there is not complete delocalization of the allyl functionality. The C(1)–C(2)–C(3) bond angle [103.2 (4)°] is much smaller than in any of the other cases due to ring strain of the five-membered ring of which it is part. This also results in a C(2)-C(1)-P bond angle of 98.1 (3)° which is smaller than the C(2)-C(1)-S bond angle of 2a of 106.4 (3)°.

The ¹H NMR spectrum of 2a is summarized in Table III, together with the assignments of the observed resonances. In the ¹H NMR spectrum of 2a, two methylene proton resonances are observed as sharp singlets at 4.08 and 4.20 ppm, each integrating for one proton. This indicates that these protons are inequivalent. Their upfield shifts confirm that the organic fragment has lost its allenic character. The SCH_3 resonance at 2.48 ppm is further downfield than those usually observed for equatorial or axial bridging SCH₃ groups in Fe₂(CO)₆ complexes (~ 1.6-2.3 ppm), in agreement for a different mode of bonding of the SCH₃ group of 2a. The ¹³C NMR resonances due to the terminal carbon atoms of the π -allyl portion of the organic ligand in 2a are somewhat upfield from the range of terminal allene carbon atom shifts (~75-95 ppm), which provides further confirmation that the organic fragment is not allenic.

The ¹³C NMR spectrum of **2a** is shown in Figure 2. The triplet at 66.1 ppm corresponding to the methylene carbon

⁽⁸⁾ Kolobova, N. E.; Derunov, V. V.; Batsanov, A. S.; Struchkov, Yu. T. Izv. Akad. Nauk SSSR, Ser. Khim. 1987, 1191 (Engl. transl. p 1104). (9) Arce, A. J.; DeSantis, Y.; Deeming, A. J.; Hardcastle, K. I.; Lee, R. J. Organomet. Chem. 1991, 406, 209.

⁽¹¹⁾ Lindley, P. F.; Mills, O. S. J. Chem. Soc. A 1970, 38.
(12) Cullen, W. R.; Williams, M.; Einstein, F. W. B.; Willis, A. C. J. Organomet. Chem. 1978, 155, 259.

atom of 2a does not appear in the normal 1:2:1 peak intensity ratio for a triplet. Rather, the center peak is only slightly more intense than the outer peaks. This is a result of the inequivalence of the methylene protons. These protons give rise to two separate resonances in the ¹H NMR spectrum, and it might be expected that this would lead to a doublet of doublets in the proton-coupled ¹³C NMR spectrum. In fact, it can be seen upon close inspection of the spectrum that the center peak of the triplet actually is slightly broadened in comparison with the two outer peaks. Thus, it can be deduced that the $J_{\rm CH}$ coupling constants are not sufficiently inequivalent to cause splitting into a true doublet of doublets, but enough so that distortion of the triplet is observed.

A comparison of the ¹H NMR spectrum of 2a with that of 6, a complex that also contains a monosubstituted $\eta^1:\eta^3$ -allyl ligand is of interest. As reported, the ¹H NMR spectrum of 6 shows three signals at δ 3.56, 3.73, and 4.33 ppm that were attributed to the allyl protons; the similarity to the 3.32, 4.08, and 4.20 ppm singlet resonances in the ¹H NMR spectrum of 2a is striking.

Complexes 2b and 2c have the same structure as 2a according to their ¹H and ¹³C NMR spectra. The CH₂= C=C(OCH₃)SCH₃ and CH₂=C=C(OCH₃)SC₂H₅-derived complexes most likely have the structure shown in 13.

As noted above, in the reactions of PhSCH=C=CH₂ and CH₃SCH=C=CH₂ with Fe₂(CO)₆ products of type (RSCHCCH₂)₂Fe₂(CO)₆ also were formed. The formation of such products has a precedent in the reaction of allene itself with Fe₂(CO)₉ in which 14 is produced in addition

(RS)HC.
$$CH(SR)$$
 (RS)HC. CH_2 H_2C CH_3 CH_4 CH_5 $CH_$

to 5.13 Should our (RSCHCCH₂)₂Fe₂(CO)₆ products be of this type, then two isomers would be possible: the cisoid 15 and the transoid 15'. In the case of PhSCH=C=CH₂ only one (RSCHCCH₂)₂Fe₂(CO)₆ product was detected, but with CH₃SCH=C=CH₂ two such products, whose ¹H and ¹³C NMR spectra showed them to be very similar, could be isolated.

An X-ray crystal structure of the PhSCH=C=CH₂/ $Fe_3(CO)_{12}$ deep red, crystalline 2:1 product, 15b, was obtained. The molecular structure is shown in the ORTEP plot in Figure 3. Relevant bond lengths and angles are

given in Tables IV and V. It can be seen to be similar to that of 14 in that it contains two equivalent η^3 allyl groups which are σ -bonded to each other at the central carbon atoms of the allyl groups. The PhS groups remain bonded to carbon atoms as substituents on the allyl groups, in cisoid orientation as in 15. They are not coordinated to iron atoms. The iron atoms in 15 and 15' are coordinatively saturated since the η^3 allyl moieties are three-electron donors, so the PhS groups remain free.

Complex 15b has a saw-horse structure, typical of complexes containing the Fe₂(CO)₆ moiety, which is capped by the diallyl fragment. This complex is highly symmetrical, having an approximate mirror plane bisecting the Fe-Fe bond and the diallyl fragment, as seen by a comparison of the parameters in the two halves of the molecule (see Tables IV and V). This symmetry is also seen in the torsion angles about the Fe-Fe bond, ranging from only 1.6 (1)° to 3.7 (2)°, indicating that the substituents on the

two Fe centers are essentially eclipsed. The lack of exact mirror symmetry results from the orientations of the phenyl substituents, which are twisted by 72.0 (1)° to each other. Within the diallyl fragment the parameters are typical of η^3 -allyl groups; ¹⁴ the C-C distances within each allyl fragment (range: 1.410 (3)-1.423 (3) Å) are essentially as expected, and the C(8)-C(11) bond between the two alkyl moieties (1.483 (3) Å) represents a normal single bond between sp² carbons. In addition, all angles within the diallyl group itself are close to the expected 120°. As is also typically the case, 14 the central carbon of each allyl group is closer to the metals (2.043 (2), 2.030 (2) Å) than are the outer carbons (range 2.106(2)-2.123(3) Å), even though each allyl plane is inclined slightly such that the central carbon is tipped away from the metal. This tipping of the allyl planes is clearly seen in a least-squares plane calculation15 involving the six carbons of the diallyl group, which shows that C(8) and C(11) lie 0.100 (3) A and 0.105 (3) Å, respectively, above this plane, whereas the others lie below this plane, toward the Fe atoms, by between 0.021 (3) and 0.082 (3) Å. Such tipping has been explained in terms of overlap between the metal and allyl orbitals. 16 The present dially unit is unusual in the positioning of the substituents on the terminal carbons of the allyl groups. Usually the anti substituents (to the C(8)-C(11) bond in this case) are displaced toward the metal whereas the syn substituents are displaced away from the metal;14 in compound 15b the opposite is found. The sulfur atoms (0.612 (1) and 0.640 (1) Å) and the anti protons on C(9)and C(12) (0.29 (3), 0.19 (3) Å) are displaced away from the Fe atoms, whereas all syn hydrogen are displaced, by between 0.05 (3) and 0.19 (3) Å, toward the Fe atoms. It appears that this anomaly results from steric repulsions between the axial carbonyls (C(1)O(1) and C(4)O(4)) and the anti substituents, since the contacts between these groups (C(1)-H(2C9) = 2.53(2) Å, C(4)-H(1C12) = 2.52(2) A; S(1)-C(1) = 2.915 (3), S(2)-C(4) = 2.910 (3) A) are less than the normal van der Waals contacts of ca. 3.0 and 3.7 Å, respectively.¹⁷ Surprisingly, C(7) and C(10), having

(16) Kettle, S. F. A; Mason, R. J. Organometal. Chem. 1966, 5, 573.

the large SPh substituents, are actually slightly closer to the Fe atoms (2.106 (2), 2.108 (2) Å) than are the other ends of the allyl groups (2.123 (3), 2.122 (3) Å) which have only hydrogen substituents, in spite of potentially more severe van der Waals repulsions involving the former. It is also noteworthy that the C(7)-C(8) and C(10)-C(11) bonds within the allyl groups are longer (1.423 (3) Å) than those involving C(9) and C(12) (1.415 (3), 1.410 (3) \mathring{A}). Taken together these observations suggest that the σ,π resonance formulation (F) may make a significant contribution to the bonding.

All sulfur-carbon distances are normal, although those involving the phenyl groups are somewhat shorter than those to the allyl moieties. This difference is consistent with the expected rehybridization of the allyl carbons toward sp³ upon coordination to the metals. It is significant however that this difference in S-C distances is also consistent with the involvement of a σ,π bonding model as suggested.

An interesting feature of the structure of this complex is the long Fe-Fe bond: 2.9767 (5) Å (compared with 2.6177 (9) for the Fe-Fe bond distance of 2a). This elongation is presumably due to the large size of the organic ligand that bridges the two iron atoms. The difference between these two Fe-Fe distances is a good example of the flexibility of the Fe₂(CO)₆ unit in its accommodation to the ligands which bridge the iron atoms.

The two (CH3SCHCCH2)2Fe2(CO)6 products were obtained only in low yield. They were difficult to separate from one another, but very slow medium-pressure column chromatography (pentane eluant) was successful. Their EI mass spectra gave identical patterns of fragmentation. Both gave acceptable C, H analyses for the (CH₃SCHCC- H_2 ₂ $Fe_2(CO)_6$ composition. Thus it was very probable that they were isomeric species, most likely the cisoid and transoid forms, 15a and 15'a (R = CH₃), respectively.

In Table VI are compared the ¹H and ¹³C NMR spectra of the two (CH₃SCHCCH₂)₂Fe₂(CO)₆ isomers and (PhSCHCCH₂)₂Fe₂(CO)₆, 15b. The ¹H NMR spectrum of one of the isomers more nearly matches that of 15b than does that of isomer 15'a. The methylene proton resonances of 15b at 2.89 and 3.70 ppm are separated by 0.81 ppm as are those of isomer 15a. In contrast, those of isomer 15'a are separated by 0.40 ppm, suggesting that the CH₂ environments of 15b and isomer 15a are similar. The chemical shifts of the central carbon atoms of the diallyl ligands in the ¹³C NMR of all three compounds in Table VI are within 1.5 ppm of one another, which indicates that the allyl groups of isomers 15a and 15'a are bonded to iron in a manner analogous to the bonding in 15b. If isomer 15a is assigned the cisoid structure, then isomer 15'a must be the transoid species.

It is of interest to consider the route by which the products of types 2 and 15 are formed in reactions of thioallenes with Fe₃(CO)₁₂. The (RSCHCCH₂)Fe₂(CO)₆ complexes, 2, might be formed as suggested in Scheme I. The first step is η^2 (π) coordination of the allene to Fe₃-

 $(CO)_{12}$. In support of this suggestion, we note that Ben-Shoshan and Pettit found that tetramethylallene reacts with Fe₂(CO)₉ to give the π -complex 16 as well as the η^4 -diene complex 17 (eq 1). Loss of Fe(CO)₅, π -com-

plexation of the entire allene and σ -bond formation between the uncomplexed iron atom and the central carbon atom of the η^3 -allyl ligand then follow. The final step is substitution of a CO ligand by the RS group, a process facilitated by the close (intramolecular) proximity of the sulfur donor atom to the iron atom.

It seemed reasonable to suppose that the use of an excess of the thioallene with respect to Fe₃(CO)₁₂ would result in formation of the (RSCHCH₂)₂Fe₂(CO)₆ products, 15 and 15', in higher yield. Such, however, was not the case, as the results in Table VII show. Reactions of two equivalents of RSCH=C=CH₂ (R = CH₃ and Ph) with $Fe_3(CO)_{12}$ resulted in nearly the same yields. Another possibility that was considered by carrying out appropriate experiments was that the type 2 complex is an intermediate in the formation of 15 and 15'. Several attempts to effect a reaction of 2a and 2b with an excess of the respective thioallene in refluxing THF solution resulted only in recovery of the respective $(\mu - \eta^1 : \eta^2 - RSCHCCH_2)Fe_2(CO)_6$ complex. No 15 or 15' type product was formed. This suggests that 15 and 15' are formed by a separate, independent process in which two molecules of the thioallene become π -coordinated to a single molecule of Fe₃(CO)₁₂ with loss of one CO ligand. Loss of Fe(CO)₅ would leave no site available for σ bonding to either thioallene molecule so that C–C bond formation at C_{β} to link the two allene molecules results instead. This would leave each as an allyl moiety which bonds to iron in the η^3 manner. However, in the absence of stronger experimental support, these suggestions concerning the course of these reactions remain only speculation.

As noted above, the formation of $(\mu\text{-RS})_2\text{Fe}_2(\text{CO})_6$ in these RSCH—C—CH₂/Fe₃(CO)₁₂ reactions is an indication of the occurrence of C–S bond cleavage. The allenyl group that would result from such cleavage may end up as a ligand on iron to give a $(\mu\text{-}\eta^1:\eta^2\text{-allenyl})$ iron carbonyl complex, but we have not been able to isolate a stable product of this kind. The possibility of the formation of wholly organic products derived from the allenyl group was not examined.

Experimental Section

General Comments. All reactions were carried out under an atmosphere of prepurified tank nitrogen. Tetrahydrofuran (THF) was distilled under nitrogen from sodium/benzophenone ketyl and purged with nitrogen prior to use. Triiron dodecacarbonyl was prepared according to a literature procedure. 18 1-Methoxy-1-methylthioallene, 19a 1-methoxy-1-ethylthioallene, 19b (phenylthio)allene, 19c and (ethylthio)allene, 19b (phenylthio)allene, 19c and (ethylthio)allene prepared by literature procedures and were purged with nitrogen before use. Dimethyl disulfide, diethyl disulfide, di-tert-butyl disulfide, thiophenol, methyl propargyl ether, 1-(dimethylamino)-2-propyne, and propargyl chloride (all purchased from Aldrich) were purged with nitrogen and used without further purification. Ammonia was passed through a column of KOH pellets before use to remove water.

The progress of all reactions was monitored by thin layer chromatography (Baker Flex, Silica Gel 1B-F). Purification was achieved by filtration chromatography in which the reaction products were dissolved in a suitable solvent and chromatographed on a bed of Mallinckrodt 100 mesh silicic acid (ca. 150 mL) in a 350-mL glass fritted filter funnel. Further purification was accomplished by thin-layer chromatography on preparative TLC plates (EM Science 60 F $_{254}$, silica gel, $20\times20\times0.025$ cm). In addition, column chromatography was used as needed and was accomplished with a 450 \times 25 mm medium-pressure column using Sigma S-0507 230-400 mesh silica gel. All chromatography was carried out without exclusion of atmopheric moisture or oxygen. Solid products were recrystallized at -20 °C. All yields are based on Fe unless otherwise indicated.

Solution or thin film infrared spectra (NaCl windows) were obtained using a Perkin-Elmer Model 1430 double-beam grating infrared spectrophotometer or a Perkin-Elmer 1600 Series FTIR instrument. Proton NMR spectra were recorded on either a Bruker WM-250, a Varian Gem-300, or a Varian XL-300 spectrometer operating at 250, 300, or 300 MHz, respectively. Carbon-13 NMR spectra were recorded on either a Varian Gem-300, or a Varian XL-300 spectrometer, operating at 75.5 and 75.4 MHz. Electron-impact mass spectra were obtained using a Finnigan-3200 mass spectrometer operating at 70 eV. The FD mass spectrum was obtained with a Finnigan MAT-731 mass spectrometer operating in the positive ion mode. Masses were correlated using the following isotopes: ¹H, ¹²C, ¹⁶O, ³²S, and ⁵⁶Fe. Melting points were determined in air on a Büchi melting-point apparatus using analytically pure samples and are uncorrected. Microanalyses were performed by Scandinavian Microanalytical Laboratory, Herley, Denmark.

X-ray Crystallography. Structure of $(\eta^1:\eta^3$ -CH₂SCHCCH₂)Fe₂(CO)₆, 2a. A suitable quality, red block crystal of $(\eta^1,\eta^3$ -CH₃SCHCCH₂)Fe₂(CO)₆ (which had been grown in pentane at -20 °C) was mounted on a glass fiber. All measurements were made on an Enraf-Nonius CAD-4 diffractometer with

graphite monochromated Mo K α radiation.

Cell constants and an orientation matrix for data collection, obtained from a least-squares refinement using the setting angles of 25 carefully centered reflections in the range $30.00 < 2\theta < 40.00^{\circ}$ corresponding to a monoclinic cell with dimensions given in Table VIII. For Z = 4 and FW = 365.91, the calculated density is 1.823 g/cm^3 . On the basis of systematic absences of h0l: $h \neq 2n$ and 0k0: $k \neq 2n$ and the successful solution and refinement of the structure, the space group was determined to be $P2_1/c$ (No. 14).

The data were collected at a temperature of 23 ± 1 °C using the ω -2 θ scan technique to a maximum 2 θ value of 54.9°. Moving-crystal moving-counter background measurements were made by scanning an additional 25% above and below the scan range.

Of the 3415 reflections which were collected, 3185 were unique $(R_{\rm int} = 0.029)$; equivalent reflections were merged. The intensities of three representative reflections which were measured after every 60 min of X-ray exposure time remained constant throughout data collection, indicating crystal and electronic stability (no decay correction was applied).

An empirical absorption correction, using the program DIFA-BS,20 was applied. The data were corrected for Lorentz and polarization effects.

The structure was solved by a combination of the Patterson method and direct methods.²¹ The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in the structure factor calculation in idealized positions ($d_{C-H} = 0.95 \text{ Å}$), and were assigned isotropic thermal parameters which were 20% greater than the $B_{\text{equivalent}}$ value of the atom to which they were

The weighting scheme was based on counting statistics and included a factor (p = 0.03) to downweight the intense reflections. Plot of $\sum w(|F_o| - |F_c|)^2$ versus $|F_o|$, reflection order in data col-

lection, $\sin \theta / \lambda$, and various classes of indexes showed no unusual trends. The maximum and minimum peaks on the final difference Fourier map corresponded to 0.34 and -0.54 e⁻/Å, respectively.

Neutral atom scattering factors were taken from Cromer and Waber. Anomalous dispersion effects were included in F_{calci} 25 the values for $\Delta f'$ and $\Delta f''$ were those of Cromer.²⁶ All calculations were performed using the TEXSAN²⁷ crystallographic software package of Molecular Structure Corp.

Structure of [n³-PhSCHCCH₂]₂Fe₂(CO)₆, 15b. Deep red crystals of (η³-PhSCHCCH₂)₂Fe₂(CO)₆ were grown from pentane/CH₂Cl₂ at -20 °C. A suitable single crystal was mounted in air on a glass fiber. Data were collected on an Enraf-Nonius CAD-4 diffractometer at 22 °C using graphite monochromated Mo K α radiation. A summary of data collection details and crystal data appears in Table VIII. Data collection and structure solution and refinement proceeded as described for compound 2a. Allyl hydrogen atoms were refined, having isotropic thermal parameters, whereas those on the phenyl rings were input as fixed contributions as described for compound 2a.

Reaction of Fe₃(CO)₁₂ with 1-Methoxy-1-(methylthio)allene at Reflux. A 100-mL three-necked, round-bottomed flask equipped with a stir bar, a reflux condenser with a gas inlet adapter, a glass stopper, and a rubber septum (standard apparatus) was charged with 1.50 g (2.98 mmol) of Fe₃(CO)₁₂ and degassed by three evacuation/nitrogen-backfill cycles. THF (30 mL) and 1-methoxy-1-(methylthio)allene (0.46 g, 4.00 mmol) then were added. The reaction mixture was stirred at gentle reflux for 4 h until TLC showed that all of the Fe₃(CO)₁₂ had been consumed. A color change from dark green to deep red was observed during the reaction time. TLC indicated that all of the Fe₃(CO)₁₂ had been consumed. The solvent was removed in vacuo to leave an oily, red residue which was dissolved in pentane/ CH₂Cl₂ (4:1 v/v) and filtered through a thin pad of silicic acid. Pentane eluted an orange band which gave 0.11 g (0.29 mmol, 19% based on S, a/e:e/e = 2.3) of $(\mu$ -CH₃S)₂Fe₂(CO)₆, identified by comparison of its ¹H NMR spectrum (CDCl₂, 250 MHz) to that of an authentic sample.28 Further elution with pentane/CH2Cl2 (5:1 v/v) gave a second orange band which yielded 0.57 g (1.43 mmol, 48%) of $(\eta^1, \eta^3$ -CH₃S(CH₃O)CCCH₂)Fe₂(CO)₆, 13a, as an air-stable, dark red-orange, crystalline solid after purification on preparative TLC plates (pentane eluant) and recrystallization from pentane/CH₂Cl₂ (3:1 v/v), mp 84.0-85.0 °C

Anal. Calcd for $C_{11}H_8Fe_2O_7S$: C, 33.36; H, 2.04. Found: C, 33.59; H, 2.14%. IR (CCl₄, cm⁻¹): 3000 (vw), 2933 (vw), 2841 (vw), 1548 (w), 1468 (w), 1440 (w), 1424 (w), 1308 (w), 1216 (m), 1188 (w), 1085 (s), 1013 (m), 972 (w), 944 (w), 748 (s), 711 (m), 671 (w), 624 (s), 596 (s), 580 (s). Terminal carbonyl region: 2067 (vs), 2025 (vs), 1994 (vs), 1969 (vs). ¹H NMR (CDCl₃, 300 MHz): δ 2.41 (s, 3 H, SCH₃), 3.24 (s, 3 H, OCH₃), 3.95 (s, 1 H, —CH₂), 4.13 (s, 1 H, —CH₂). ¹³C NMR (CDCl₃, 75.5 MHz): δ 29.23 (q, J_{CH} = 142.3 Hz, SCH₃), 54.20 (q, J_{CH} = 145.4 Hz, OCH₃), 162.00 (s, allyl C), 210.45 (s, terminal CO's). Mass spectrum (EI) m/z (rel intensity): 396 (M⁺, 24), 368 (M⁺ – CO, 58), 340 (M⁺ – 2CO, 58), 312 (M⁺ – 3CO, 100), 284 (M⁺ – 4CO, 57), 256 (M⁺ – 5CO, 74), 228 (M⁺ – 6CO, 89), 198 (Fe₂(MeS)C—C—CH₂⁺ + 1 H, 74), 183 (Fe₂HSC—C—CH₂⁺, 14), 170 (Fe(MeO)(MeS)C—C—C⁺, 27), 144 (Fe₂S⁺, 27).

Methylene choride eluted a third orange band which appeared to be a mixture of very minor products by TLC and was discarded.

Reaction of Fe₃(CO)₁₂ with 1-Methoxy-1-(ethylthio)allene. The standard apparatus was charged with 1.50 g (2.98 mmol) of Fe₃(CO)₁₂ and degassed by three evacuation/nitrogen-backfill cycles. THF (30 mL) and 1-methoxy-1-(ethylthio)allene (0.52 g, 4.00 mmol) then were added. The reaction mixture was stirred at gentle reflux for 4 h until TLC showed that all of the Fe₃(CO)₁₂ had been consumed. The solvent was removed in vacuo to leave an oily, red residue which was dissolved in pentane/CH₂Cl₂ (4:1 v/v) and filtered through a thin pad of silicic acid. Pentane eluted an orange band which gave 0.25 g (0.63 mmol, 42% based on S, a/e:e/e = 2.2) of $(\mu$ -C₂H₅S)₂Fe₂(CO)₆,²⁸ identified by comparison of its 1H NMR spectrum (CDCl₃, 250 MHz) to that of an authentic sample. Further elution with pentane/CH₂Cl₂ (3:1 v/v) gave a second orange band which yielded 0.52 g (1.26 mmol, 42%) of $(\eta^1:\eta^3-C_2H_5S(CH_3O)CCCH_2)Fe_2(CO)_6$, 13b, as an air-stable, red, crystalline solid after purification on preparative TLC plates (pentane eluant) and recrystallization from pentane/CH₂Cl₂ (3:1 v/v), mp 136.0-138.0 °C

Anal. Calcd for $C_{12}H_{10}Fe_2O_7S$: C, 35.15; H, 2.46. Found: C, 35.27; H, 2.52%. IR (CCl₄, cm⁻¹): 2934 (vw), 1456 (w), 1440 (w), 1382 (m), 1214 (m), 1085 (s), 1013 (m), 960 (w), 710 (m), 670 (w), 624 (s), 597 (s), 581 (m). Terminal carbonyl region (CCl₄, cm⁻¹): 2066 (vs), 2024 (vs), 1996 (vs), 1984 (vs), 1968 (s). ¹H NMR (CDCl₃, 250 MHz): δ 1.37 (t, J = 7.50 Hz, 3 H, SCH₂CH₃), 2.66 (m, J = 6.85 Hz, 1 H, SCH₂CH₃), 2.95 (m, J = 6.80 Hz, 1 H, SCH₂CH₃), 3.26 (s, 3 H, OCH₃), 3.93 (s, 1 H, \rightleftharpoons CH₂), 4.11 (s, 1 H, \rightleftharpoons CH₂). ¹³C NMR (CDCl₃, 75.5 MHz): δ 12.89 (q, J_{CH} = 129.4 Hz, SCH₂CH₃), 42.12 (t, J_{CH} = 142.6 Hz, SCH₂CH₃), 54.52 (q, J_{CH} = 144.9 Hz, OCH₃), 68.18 (t, J_{CH} = 162.3 Hz, \rightleftharpoons CH₂), 113.56 (s, CH₃CH₂SCOCH₃), 162.48 (s, allyl C), 210.62 (s, terminal CO's). Mass spectrum (EI) m/z (rel intensity): 410 (M⁺, 17), 382 (M⁺ – CO, 36), 354 (M⁺ – 2CO, 34), 326 (M⁺ – 3CO, 55), 298 (M⁺ –

4CO, 36), 270 (M $^+$ - 5CO, 63), 242 (M $^+$ - 6 CO, 91), 214 (Fe₂HSC(OMe)—C—CH₂ $^+$, 46), 184 (Fe₂HSCH—C—CH₂ $^+$, 100), 182 (Fe₂SC—C—CH₂ $^+$, 33), 170 (Fe₂HSCH—C $^+$, 7), 144 (Fe₂S $^+$, 53), 112 (Fe₂ $^+$, 6), 56 (Fe $^+$, 18), 40 (CH₂—C—CH₂, 11).

Reaction of Fe₃(CO)₁₂ with 1-Methoxy-1-(tert-butylthio)allene. The standard apparatus was charged with 1.50 g (2.98 mmol) of Fe₃(CO)₁₂ and degassed by three evacuation/nitrogen-backfill cycles. THF (30 mL) and 1-methoxy-1-(tert-butylthio)allene (0.63 g, 4.00 mmol) then were added. The reaction mixture was stirred at gentle reflux for 4 h until TLC showed that all of the Fe₃(CO)₁₂ had been consumed. The solvent was removed in vacuo to leave an oily, red residue which was dissolved in pentane/CH₂Cl₂ (5:1 v/v) and filtered through a thin pad of silicic acid. Pentane eluted an orange band which gave 0.51 g (1.11 mmol, 74% based on S, a/e:e/e = 3.1) of (μ -t-BuS)₂Fe₂(CO)₆, identified by comparison of its ¹H NMR spectrum (CDCl₃, 250 MHz) to that of an authentic sample.²⁹ Further elution with pentane/CH₂Cl₂ (3:1 v/v) gave a very minor orange band which was not collected.

Reaction of Fe₃(CO)₁₂ with (Methylthio)allene. The standard apparatus was charged with 1.50 g (2.98 mmol) of Fe₃(CO)₁₂ and degassed by three evacuation/nitrogen-backfill cycles. THF (30 mL) and (methylthio)allene (0.34 g, 4.00 mmol) then were added. The reaction mixture was stirred at gentle reflux for 5 h until TLC showed that all of the Fe₃(CO)₁₂ had been consumed. The solvent was removed in vacuo to leave an oily, red residue which was dissolved in pentane/CH₂Cl₂ (4:1 v/v) and filtered through a thin pad of silicic acid. Pentane eluted an orange band which gave 0.03 g (0.08 mmol, 5% based on S, a/e:e/e = 2.1) of (μ-CH₃S)₂Fe₂(CO)₆, identified by comparison of its ¹H NMR spectrum to that of an authentic sample. Further elution with pentane/CH₂Cl₂ (5:1 v/v) gave a second orange band which yielded 0.47 g (1.29 mmol, 43%) of $(\eta^1, \eta^3$ -CH₃SCHČCH₂)Fe₂(CO)₆, 2a, as an air-stable, deep red, crystalline solid after purification on preparative TLC plates (pentane eluant) and recrystallization from pentane, mp 53.0-55.0 °C.

Anal. Calcd for $C_{10}H_6Fe_2O_6S$: C, 32.82; H, 1.66. Found: C, 33.11; H, 1.75%. IR (CCl₄, cm⁻¹): 2965 (w), 2930 (w), 2860 (w), 1465 (w), 1425 (w), 1310 (w), 1190 (w), 955 (w), 925 (w), 700 (m), 620 (m), 605 (w), 575 (m). Terminal carbonyl region (CCl₄, cm⁻¹): 2070 (s), 2030 (vs), 2010 (sh), 1990 (vs), 1950 (vs). ¹H NMR (CDCl₃, 300 MHz): δ 2.48 (s, 3 H, SCH₃), 3.32 (s, 1 H, CH₃SCH), 4.08 (s, 1 H, —CH₂), 4.20 (s, 1 H, —CH₂). ¹³C NMR (CDCl₃, 75.5 Mhz): δ 33.21 (q, $J_{\rm CH}$ = 141.7 Hz, SCH₃), 66.00 (d, $J_{\rm CH}$ = 188.0 Hz, CH₃SCH), 67.88 (t, $J_{\rm CH}$ = 161.6 Hz, —CH₂), 175.46 (s, allyl C), 209.04, 212.20 (both s, terminal CO's). Mass spectrum (EI) m/z (rel intensity): 366 (M⁺, 15), 338 (M⁺ – CO, 29), 310 (M⁺ – 2CO, 56), 282 (M⁺ – 3CO, 20), 254 (M⁺ – 4CO, 35), 226 (M⁺ – 5CO, 24), 198 (M⁺ – 6CO, 100), 183 (Fe₂SCH—C—CH₂⁺, 36), 170 (Fe₂SCH—CH⁺, 27), 144 (Fe₂S⁺, 31).

Methylene chloride eluted a third orange band which, after slow medium pressure column chromatography with pentane as the eluant gave two orange-red bands. The first band to elute gave 0.07 g (0.16 mmol, 5%) of transoid-(η^3 -CH₃SCHCCH₂)₂Fe₂(CO)₆, 15'a as an air-stable, orange-red, crystalline solid after recrystallization from pentane, mp 99.0–100.0 °C.

Anal. Calcd for $C_{14}H_{12}Fe_2O_8S_2$: C, 37.19; H, 2.68. Found: C, 36.80; H, 2.95%. IR (CCl₄, cm⁻¹): 2917 (w), 1555 (w), 1540 (w), 1456 (m), 1130 (w), 659 (w), 593 (m), 569 (m), 544 (s), 525 (w), 508 (w). Terminal carbonyl region (CCl₄, cm⁻¹): 2064 (vs), 2060 (vs), 2027 (vs), 1995 (vs). 1 H NMR (CDCL₃, 300 MHz): δ 2.12 (s, 3 H, SCH₃), 2.65 (t, J = 1.87 Hz, 1 H, CH₃SCH), 2.84 (d, J = 2.69 Hz, 1 H, —CH₂), 3.24 (d, J = 1.70 Hz, 1 H, —CH₂). 13 C NMR (CDCl₃, 75.4 MHz): δ 20.48 (q, J_{CH} = 140.0 Hz, SCH₃), 44.64 (t, J_{CH} = 164.2 Hz, —CH₂), 58.67 (d, J_{CH} = 168.7 Hz, CH₃SCH), 87.38 (s, allyl C), 208.65, 211.20, 216.36 (both s, terminal CO's). Mass spectrum (EI) m/z (rel intensity): 424 (M⁺ - CO, 9), 396 (M⁺ - 2CO, 51), 368 (M⁺ - 3CO, 14), 340 (M⁺ - 4CO, 28), 312 (M⁺ - 5CO, 29), 284 (M⁺ - 6CO, 71), 269 (Fe₂(MeSCH—C—CH₂)-(SCH—C—CH₂+, 30), 254 (Fe₂(SCH—C—CH₂)₂+, 20), 235 (Fe₂(MeSC—C—CH₂)(C—C—CH₂)+, 15), 191 (Fe₂(CH₂—C—CH)₂+ + 1H, 64), 177 (Fe₂(CH₂—C—CH)(CH₂—C)+, 31), 176 (Fe₂(CH₂—C—C)(CH₂—C)+, 100), 144 ((HSCH—C—CH₂)+, 34),

142 (SCH=C=CH₂)₂⁺, 16), 97 ((CH₂=C=CH)(HSCH=C)⁺, 20), 83 (CH₂=C)(SCH=C)⁺, 17), 56 (Fe⁺, 17).

The second band to elute yielded 0.06 g (0.13 mmol, 4%) of cisoid- $[\eta^3$ -CH₃SCHCCH₂]₂Fe₂(CO)₆, 15a, as an air-stable, orange-red, crystalline solid after recrystallization from pentane, mp 96.0–98.0 °C.

Anal. Calcd for $C_{14}H_{12}Fe_2O_6S_2$: C 37.19; H, 2.68. Found: C, 37.60; H, 2.85%. Reaction of Fe₃(CO)₁₂ with (Phenylthio)allene. The standard apparatus was charged with 1.50 g (2.98 mmol) of Fe₃(CO)₁₂ and degassed by three evacuation/nitrogen-backfill cycles. THF (30 mL) and (phenylthio)allene (0.59 g, 4.00 mmol) then were added. The reaction mixture was stirred at gentle reflux for 1.5 h until TLC showed that all of the Fe₃(CO)₁₂ had been consumed. The solvent was removed in vacuo to leave an oily, red residue which was dissolved in pentane/CH₂Cl₂ (1:4 v/v) and filtered through a thin pad of silicic acid. Elution with pentane/CH₂Cl₂ (5:1 v/v) gave an orange band which yielded 0.37 g (0.85 mmol, 29%) of ($\eta^1:\eta^3$ -PhSCHCCH₂)Fe₂(CO)₈, 2b, as air-stable, orange-red, crystalline solid after purification on preparative TLC plates (pentane/CH₂Cl₂ (1:1 v/v) eluant) and recrystallization from pentane/CH₂Cl₂ (2:1 v/v), mp 107.0–109.0 °C.

Anal. Calcd for $C_{15}H_8Fe_2O_6S$: C, 42.09; H, 1.89. Found: C, 42.17; H, 1.93%. IR (thin film, cm⁻¹): 2359 (w), 1644 (w), 1441 (w), 1068 (w), 740 (m), 702 (m), 622 (m). Terminal carbonyl region (CCl₄, cm⁻¹): 2070 (s), 2028 (vs), 1997 (vs), 1975 (s). ¹H NMR (CDCl₃, 300 MHz): δ 3.52 (s, 1 H, PhSCH), 4.12 (s, 1 H, —CH₂), 4.34 (s, 1H, CH₂), 7.39–7.67 (m, Ph). ¹³C NMR (CDCl₃, 75.4 MHz): δ 62.23 (d, J_{CH} = 181.3 Hz, PhSCH), 67.76 (t, J_{CH} = 161.3 Hz, —CH₂), 126.88 (d, J_{CH} = 162.6 Hz, Ph), 129.12 (d, J_{CH} = 165.9 Hz, Ph), 129.54 (d, J_{CH} = 163.4 Hz, Ph), 139.70 (s, ipso Ph), 174.30 (s, allyl CO), 209.20, 211.86 (both s, terminal CO's). Reaction of Fe₃(CO)₁₂ with (Ethylthio)allene. The standard apparatus was charged with 1.50 g (2.98 mmol) of Fe₃(CO)₁₂ and degassed by three evacuation/nitrogen-backfill cycles. THF (30 mL) and (ethylthio)allene (0.40 g, 4.00 mmol) then were added. The reaction mixture was stirred at gentle reflux for 1 h until TLC showed that all of the Fe₃(CO)₁₂ had been consumed. The solvent was removed in vacuo to leave an oily, red residue which was dissolved in pentane/CH₂Cl₂ (1:1 v/v) and filtered through a thin pad of silicic acid. Elution with pentane gave an orange band which yielded 0.55 g (1.38 mmol, 93%, a/e:e/e = 2.3) of (μ -C₂H₅S)₂Fe₂(CO)₆, identified by comparison of its ¹H NMR spectrum to that of an authentic sample. Further elution with pentane/CH₂Cl₂ (4:1 v/v) gave 0.06 g (0.15 mmol, 5%) of $(\eta^1:\eta^3-C_2H_5SCHCCH_2)Fe_2(CO)_6$, 2c, as a red-orange, oil, which was identified by comparison of its ¹H NMR spectrum to that of $(\eta^1, \eta^3$ -CH₃SCHCCH₂)Fe₂(CO)₆, 2a. However, this product could not be obtained in a pure form, even after repeated chromatography and further characterization was not completed.

¹H NMR (CDCl₃, 250 MHz): δ 1.32 (t, J = 7.32 Hz, 3 H, SCH₂CH₃), 2.72 (m, J = 7.41 Hz, 1 H, SCH₂CH₃), 2.81 (m, J = 7.48 Hz, 1 H, SCH₂CH₃), 3.31 (s, 1 H, EtSCH), 4.07 (s, 1 H, =-CH₂), 4.27 (s, 1 H, =-CH₂).
