**Supporting Information** 

ABSTRACT: A series of benzo-linked phosphine-diethyl phosphonate (P-PO) and phosphine-bis(diethyl phosphonate)  $(P-(PO)_2)$ ligands and the corresponding (P-PO)PdMe(2,6-lutidine)<sup>+</sup> and (P- $(PO)_2$ )PdMe(2,6-lutidine)<sup>+</sup> complexes were synthesized. Cationic (P-PO)PdMe(2,6-lutidine)<sup>+</sup> complexes are active for ethylene oligomerization/polymerization, with activities of 2 kg mol<sup>-1</sup> h<sup>-1</sup> for  $\{\kappa^2 - 1 - P^i Pr_2 - 2 - P(O)(OEt)_2 - 5 - Me - Ph\}PdMe(2, 6 - lutidine)^+$  (3c),

125 kg mol<sup>-1</sup> h<sup>-1</sup> for { $\kappa^2$ -1-PPh<sub>2</sub>-2-P(O)(OEt)<sub>2</sub>-5-Me-Ph}PdMe-(2,6-lutidine)<sup>+</sup> (3a), and 1470 kg mol<sup>-1</sup> h<sup>-1</sup> for { $\kappa^2$ -1-P(2-OMe-Ph)<sub>2</sub>-2-P(O)(OEt)<sub>2</sub>-Ph}PdMe(2,6-lutidine)<sup>+</sup> (3b). The polyethylene is highly linear, with over 80% terminal unsaturation and low (230-1890 Da) molecular weight in all cases. 3b copolymerizes ethylene with methyl acrylate, exhibiting highly selective (95%) in-chain (rather than chain-end) acrylate incorporation. The P-(PO)<sub>2</sub> catalyst { $\kappa^2$ -1-P(4-<sup>t</sup>Bu-Ph)(2-P(O)(OEt)<sub>2</sub>-5-Me-Ph)-2-P(O)(OEt)<sub>2</sub>-5-Me-Ph}PdMe(2,6-lutidine)<sup>+</sup> (3d) is more active for ethylene homopolymerization (2640 kg mol<sup>-1</sup> h<sup>-1</sup>), yielding linear, low-molecular-weight polymer (1280–1430 Da) with predominantly internal olefin placement. In ethylene/methyl acrylate copolymerization, 3d incorporates 2.6 mol % methyl acrylate, 60% of which is in-chain. Both 3b and 3d catalyze ethylene/acrylic acid copolymerization, albeit with low (<10 kg mol<sup>-1</sup> h<sup>-1</sup>) activities and acrylic acid incorporation up to 1.1 mol %.

## ■ INTRODUCTION

Palladium(II) alkyl complexes that contain ortho-phosphinoarenesulfonate (PO) ligands (A, Chart 1) polymerize ethylene to highly linear polyethylene (PE),<sup>1</sup> and the catalyst activity and the polyethylene molecular weight are strongly influenced by the substituents on the phosphine unit (R) and the lability of the L ligand.<sup>2</sup> These catalysts also copolymerize ethylene with a wide variety of polar vinyl monomers, yielding functionalized linear copolymers with both in-chain and chain-end incorporation of the comonomer.<sup>3–8</sup> However, the ethylene polymerization activities and polymer molecular weights exhibited by (PO)PdMeL catalysts are low compared to those for other families of single-site catalysts,<sup>9</sup> and polar monomers invariably decrease activities and molecular weights.

The combination of a strong (phosphine) and weak (sulfonate) donor in the ancillary PO ligand in (PO)PdR catalysts is believed to suppress  $\beta$ -hydride elimination processes that can lead to chain walking and branched polymer chains<sup>1,10</sup> and  $\beta$ -X eliminations (X = halide, OR, O<sub>2</sub>CR) that can lead to catalyst deactivation in copolymerizations. 5b,11 Additionally, it has been proposed that the sulfonate group facilitates cis/trans isomerization of the catalyst during chain growth via formation of five-coordinate  $\kappa^{3}$ -*P*,*O*,*O*-PO species that undergo Berry pseudorotations.<sup>1,10</sup>

The behavior of (phosphine-bis(arenesulfonate))PdMeL catalysts ((OPO)PdMeL, B, Chart 1) differs dramatically from that of (PO)PdMeL species A. Phosphine-bis(arenesulfonate)PdMeL complexes self-assemble into tetrameric

aggregates through Li-sulfonate interactions involving the non-Pd-coordinated sulfonate moiety and one oxygen of the Pd-bound sulfonate. The tetrameric catalyst yields polyethylene with much higher molecular weight ( $M_w$  up to 1 000 000 Da) and incorporates more vinyl fluoride in copolymerizations compared to monomeric catalysts A. Sequestration of the Li<sup>+</sup> with Crypt211 converts the tetrameric species into a mononuclear ( $\kappa^2$ -P,O-OPO)PdMeL species with a pendant ArSO<sub>3</sub><sup>-</sup> group that oligomerizes ethylene with high activity, suggesting that the pendant arenesulfonate group strongly accelerates chain transfer.12

Bidentate phosphine-phosphine oxide ligands are similar to PO ligands in that they contain a combination of strong and weak donor groups.<sup>13</sup> Cationic Pd and Ni complexes with chelating  $\kappa^2$ -P,O-phosphine-phosphine oxide ligands have been shown to oligomerize ethylene, and the Pd complexes also catalyze ethylene/CO copolymerization.<sup>14</sup> Recently, Nozaki and co-workers reported a versatile series of such catalysts (C) that polymerize ethylene to linear PE with low polydispersity and also copolymerize ethylene with allyl acetate, allyl chloride, tert-butylvinyl ether, vinyl acetate, and acrylonitrile, but not with methyl acrylate. Variation of the phosphine and phosphine oxide substituents (R, R') yields a broad range of catalyst activities and product molecular weights, some of which are comparable to those obtained with the phosphine-sulfonate

Chart 1

catalysts.<sup>15</sup> Phosphine-dialkyl phosphonate ligands also contain strong and weak donors.<sup>16</sup> Braunstein found that cationic Pd-alkyl complexes (**D**) with a chelated phosphine-diethyl phosphonate ligand undergo CO insertion and subsequent ethylene or methyl acrylate insertion.<sup>17,18</sup>

In this paper, we report the synthesis, ethylene polymerization behavior, and ethylene/acrylate copolymerization characteristics of cationic Pd complexes that contain phosphine-(diethyl phosphonate) (E) or phosphine-bis(diethyl phosphonate) (F) ligands. The diethyl arylphosphonate group is expected to be a weaker donor than a triaryl- or dialkylarylphosphine oxide,<sup>2e,19</sup> and the presence of additional oxygen atoms may facilitate cis/trans isomerization of {phosphine-(diethyl phosphonate)}PdRL species, which may be important for chain growth, as proposed for the phosphine-sulfonate systems. The phosphine-bis(diethyl phosphonate) ligand offers the possibility of weak interactions of the non-Pd-coordinated phosphonate group with the metal or a polar comonomer, which may influence polymerization or copolymerization behavior, as observed for B. The second phosphonate group may also prolong catalyst lifetimes if ligand loss is a major deactivation pathway, or facilitate cis/trans isomerization by formation of a configurationally labile five-coordinate species.

### RESULTS AND DISCUSSION

**Triarylphosphine-Diethyl Phosphonate Complexes.** The benzo-linked phosphine-diethyl phosphonate ligands **1a** and **1b** (P-PO, Scheme 1) were synthesized as reported by Pringle<sup>16i</sup> and Rieger<sup>20</sup> and metalated by reaction with (COD)PdMeCl, yielding (P-PO)PdMeCl complexes **2a**,**2b**. The presence of P–P coupling in the <sup>31</sup>P NMR spectra of the complexes is diagnostic of ligand chelation. The free ligands **1a** and **1b** do not exhibit P–P coupling, while complexes **2a** and **2b** show a  $J_{PP}$  of 14 and 11 Hz, respectively. Small <sup>3</sup> $J_{PH}$  (**2a**,**2b**: 4 Hz) and <sup>2</sup> $J_{PC}$  (**2b**: 2 Hz) values are observed for the <sup>1</sup>H and <sup>13</sup>C PdMe resonances of **2a**,**2b**, consistent with a *cis* arrangement of the phosphine and methyl ligands.<sup>5a</sup> The

reaction of 2a,2b with AgSbF<sub>6</sub> in the presence of 2,6-lutidine yields cationic (P-PO)PdMe(2,6-lut)<sup>+</sup> species 3a,3b.

The solid-state structures of 3a and 3b are shown in Figures 1 and 2, respectively. In each case, a square-planar Pd (II)

Figure 1. Molecular structure of 3a. Hydrogen atoms and the  $SbF_6^-$  anion are omitted. Bond lengths (Å) and angles (deg): C(1)-Pd(1) 2.020(6), N(1)-Pd(1) 2.110(4), O(1)-Pd(1) 2.170(4), P(1)-Pd(1) 2.2152(16); C(1)-Pd(1)-P(1) 88.36(17), P(1)-Pd(1)-O(1) 96.34(11), O(1)-Pd(1)-N(1) 88.29(16), N(1)-Pd(1)-C(1) 87.1(2).

center is chelated by phosphorus and oxygen donor atoms, forming a puckered six-membered ring that adopts a boat conformation in 3a and a twist-boat conformation in 3b. The angle between the P-C-C-P and O-Pd-P planes is 35.8° in 3a and  $33.2^{\circ}$  in 3b. In both complexes, the plane of the 2,6lutidine ligand is perpendicular to the Pd square plane. The Pd–C distances of **3a** (2.020(6) Å) and **3b** (2.021(2) Å) are ca. 0.09 Å shorter than those in analogous neutral phosphinesulfonate complexes,<sup>5a</sup> presumably reflecting the weaker trans influence of the neutral diethyl phosphonate donor group compared to the anionic sulfonate group. The P=O distance of 3a (1.477(4) Å) is essentially unchanged from the value reported for ligand 1a (1.468(3) Å).<sup>16i</sup> The solution NMR data for 3a and 3b are consistent with the solid-state structures. Both 3a and 3b exhibit  $J_{PP}$  values of 16 Hz and  ${}^{3}J_{P,CH}$  values of 4 Hz, indicating  $\kappa^2$ -P,O coordination of the P-PO ligand and a

Figure 2. Molecular structure of 3b. Hydrogen atoms and the  $SbF_6^-$  anion are omitted. Bond lengths (Å) and angles (deg): C(1)-Pd(1) 2.021(2), N(1)-Pd(1) 2.127(2), O(3)-Pd(1) 2.1639(17), P(1)-Pd(1) 2.2353(6); C(1)-Pd(1)-N(1) 92.09(9), N(1)-Pd(1)-O(3) 83.08(7), O(3)-Pd(1)-P(1) 97.45(5), P(1)-Pd(1)-C(1) 87.46(8).

*cis* relationship of the phosphine and methyl groups. The NMR data for **2a**,**2b** and **3a**,**3b** are consistent with fast inversion of the chelate rings on the NMR time scale for these species, which is also observed in (PO)Pd(R)(L) compounds.<sup>2a,21</sup>

**Diisopropylphosphine-Diethyl Phosphonate Complexes.** An analogue of **1a,1b** with isopropyl substituents on the phosphine was synthesized by a different route. Diethyl *ortho*-bromo-arylphosphonates **4** and **5** were prepared by Pdcatalyzed P–C coupling<sup>22</sup> of the appropriate aryl bromide with diethyl phosphite by Charette's procedure (Scheme 2).<sup>23</sup>

Diethyl phosphite and triethylamine were used in excess due to competing dealkylation of the former by the amine.<sup>24</sup> 5 was lithiated by metal-halogen exchange and then reacted with  $P^iPr_2Cl$ , yielding ligand 1c as a waxy solid (Scheme 3).

The reaction of 1c with (COD)PdMeCl affords the neutral complex 2c. Subsequent chloride abstraction by  $AgSbF_6$  in the presence of 2,6-lutidine yielded cationic complex 3c. Complexes 2c and 3c exhibit P–P coupling in the <sup>31</sup>P NMR spectra (ca. 14 Hz), whereas no P–P coupling is observed in the free ligand 1c.

The solid-state structures of 2c (see the Supporting Information) and 3c (Figure 3) share several characteristics with the structures of 3a,3b. The phosphine and diethyl phosphonate moieties chelate a square-planar Pd center. The methyl group is *cis* to the phosphine, and the 2,6-lutidine is perpendicular to the Pd square plane. The chelate ring in 3c is notably less puckered than those in 3a and 3b and adopts a half-chair conformation in which the angle between P–C–C–P and O–Pd–P planes is only 13.8°. The Pd–O distance in 3c (2.118(2) Å) is significantly shorter than those in 3a (2.170(4) Å) and 3b (2.1639(17) Å).

Phosphine-Bis(diethyl phosphonate) Complexes. Phosphine-bis(diethyl phosphonate) ligands 1d-1g were

Figure 3. Molecular structure of 3c. Hydrogen atoms and the  $SbF_6^-$  anion are omitted. Bond lengths (Å) and angles (deg): C(1)-Pd(1) 2.011(4), N(1)-Pd(1) 2.111(3), O(1)-Pd(1) 2.118(2), P(2)-Pd(1) 2.2208(14); C(1)-Pd(1)-N(1) 87.04(13), N(1)-Pd(1)-O(1) 87.44(11), O(1)-Pd(1)-P(2) 95.10(8), P(2)-Pd(1)-C(1) 90.57(11).

synthesized as shown in Schemes 4 and 5. The requisite  $ArPCl_2$  components 6 and 7 were synthesized by lithiation of

the appropriate aryl bromide, reaction with  $P(NEt_2)_2Cl$ , and treatment with acid (Scheme 4). Dichlorophenylphosphine (8) was obtained commercially. 6–8 were then coupled with 2 equiv of lithiated 4 or 5 (Scheme 5), yielding a series of phosphine-bis(diethyl phosphonate) ligands. Only 1d and 1g, which were expected to best solubilize subsequent Pd complexes, were used further.

The reaction of 1d, 1g with (COD)PdMeCl yields neutral (P-(PO)<sub>2</sub>)PdMeCl complexes 2d and 2g (Scheme 6). In the solid

Scheme 6

state, 2g adopts a square-planar structure with coordination of the phosphine and one of the diethyl phosphonate moieties and a cis arrangement of the phosphine and methyl ligands (Figure 4). The noncoordinated phosphonate oxygen atom is positioned close to one axial site of the Pd center, but the P-O distance of 3.285 Å is beyond the sum of the van der Waals radii of Pd and O (3.15 Å).<sup>25</sup> The P=O bond length of the coordinated phosphonate unit (1.467(3) Å) is essentially equal to that of the noncoordinated unit (1.455(3) Å). The <sup>1</sup>H NMR spectra of 2d and 2g in CD<sub>2</sub>Cl<sub>2</sub> at room temperature each contain a single set of resonances for the  $-Ar-P(O)(OEt)_2$ rings (some are broad). The  ${}^{31}P{}^{1}H$  NMR spectra for 2d,2g at room temperature each contain a triplet for the phosphine unit  $(J_{\rm PP} = 9)$  and a single broad resonance for the phosphonate unit. These results are consistent with fast exchange on the NMR time scale of the Pd-bound and nonbound phosphonate units under these conditions.

Complex 2d was converted to the cationic 2,6-lutidine complex 3d by reaction with  $AgSbF_6$  and 2,6-lutidine (Scheme 6). Repeated efforts to crystallize this material were unsuccessful. However, NMR data establish that 3d, like 2d,2g, contains one Pd-bound and one non-Pd-bound phosphonate group, which exchange on the NMR time scale at room temperature. At 208 K, the <sup>1</sup>H NMR spectrum of 3d

Figure 4. Molecular structure of 2g. Hydrogen atoms are not shown. Bond lengths (Å) and angles (deg): C(1)-Pd(1) 2.011(4), Cl(1)-Pd(1) 2.3486(11), O(1)-Pd(1) 2.152(2), P(1)-Pd(1) 2.1873(11), P(2)-O(1) 1.467(3), P(3)-O(4) 1.455(3), O(4)-Pd(1) 3.285(3); C(1)-Pd(1)-Cl(1) 89.47(11), Cl(1)-Pd(1)-O(1) 88.51(7), O(1)-Pd(1)-P(1) 95.45(7), P(1)-Pd(1)-C(1) 86.70(11).

contains two sets of 2-P(O)(OEt)<sub>2</sub>-4-Me-Ph resonances, two 2,6-lutidine methyl resonances, and two lutidine H3 resonances (Figure 5). As the temperature is raised, these corresponding sets of resonances broaden and coalesce. Similarly, the  ${}^{31}P{}^{1}H$ spectrum of **3d** at 208 K contains two doublets (I = 20 Hz) at  $\delta$ 31.8 and 20.5, which are assigned to the phosphine and the Pdcoordinated phosphonate, and a singlet at  $\delta$  16.8, which is assigned to uncoordinated phosphonate. As the temperature is increased, the phosphine resonance evolves into a triplet with J = 9 Hz, and the phosphonate resonances broaden significantly. The activation barriers determined by line shape analysis of the 2-P(O)(OEt)<sub>2</sub>-4-CH<sub>3</sub>-Ph <sup>1</sup>H resonance, the lutidine-CH<sub>3</sub> <sup>1</sup>H resonance, and the <sup>31</sup>P resonances are identical ( $\Delta G^{\ddagger} = 14$  kcal mol<sup>-1</sup> at 272 K), indicative of the operation of a single dynamic process. Exchange of free and Pd-coordinated phosphonate groups will produce all of these dynamic NMR effects. Note that the 2,6-lutidine is expected to be oriented perpendicular to the Pd square plane, as observed for 3c and 3a,3b, and that the phosphonate exchange is sufficient to permute the lutidine methyl groups and the H3 hydrogen atoms.

Ethylene Homopolymerization by Phosphine-Diethyl Phosphonate and Phosphine-Bis(diethyl phosphonate) **Complexes.** Complexes 3a,3b oligomerize/polymerize ethylene to linear low-molecular-weight PE (Table 1). At 80 °C and 28 atm ethylene, 3a yields a Schulz-Flory distribution of  $C_6$ - $C_{22} \alpha$ -olefins (>95% terminal olefins), with an activity of 125 kg mol<sup>-1</sup> h<sup>-1</sup> (entry 1).<sup>26</sup> The methoxy substituents in catalyst **3b** significantly alter the polymerization characteristics. Under the same conditions, for 3b,  $M_n$  is increased more than 7-fold to 1760 Da, the activity is increased to 1470 kg mol<sup>-1</sup> h<sup>-1</sup>, and the selectivity for  $\alpha$ -olefin (rather than internal olefin) formation upon chain transfer is 92% (entry 3). The  $T_{\rm m}$  values for the PEs produced by 3a (72 °C) and 3b (126 °C) are consistent with the low molecular weights.<sup>27</sup> In comparison, the [(phosphinephosphine oxide)PdMe(lut)][SbF<sub>6</sub>] catalysts (B, Chart 1) reported by Nozaki exhibit activities ranging from 36 to 340 kg  $mol^{-1} h^{-1}$  when run under similar conditions (80 °C, 30 atm, in toluene), with polymer  $M_n$  values between 800 Da and 39

**Figure 5.** Variable-temperature NMR spectra of 3d. (a) The phosphine (left) and phosphonate (right) regions of the  ${}^{31}P{}^{1}H$  spectra. (b) The lutidine- $CH_3$  (downfield) and 2-P(O)(OEt)<sub>2</sub>-4- $CH_3$ -Ph (upfield) regions of the  ${}^{1}H$  NMR spectra.

kDa.<sup>15</sup> The phosphine-diethyl phosphonates reported here, therefore, span a much broader, generally higher range of activities, but the polymer molecular weights are lower.

Surprisingly, diisopropylphosphine-diethyl phosphonate complex 3c exhibited the lowest activity of those tested, less than 2.2 kg mol<sup>-1</sup> h<sup>-1</sup> (entries 4–6). The small amount of polymer produced was found to have a low molecular weight  $(M_n < ca. 570 \text{ Da}).^{28}$  In an effort to avoid possible catalyst decomposition at elevated temperature, a polymerization was attempted at 40 °C, but no polymer was formed (entry 6). These results contrast with trends observed in other catalysts. The most active phosphine-phosphine oxide based catalysts within the series studied by Nozaki and co-workers were those with diisopropyl-substituted phosphines. Similarly, in phosphine-sulfonate systems, Claverie et al. found that catalysts with alkyl substituents on the phosphine are typically more active than those with aryl groups.<sup>2d</sup>

The phosphine-bis(diethyl phosphonate) complex 3d was found to be highly active for ethylene polymerization. The activity exhibits more variation with pressure than observed for **3b**, increasing from 1150 kg mol<sup>-1</sup>  $h^{-1}$  at 17 atm to 2640 kg mol<sup>-1</sup> h<sup>-1</sup> at 28 atm (entries 7 and 8). The PE molecular weight varies minimally over this pressure range, from 1400 to 1500 Da, with PDI values just under 2. In contrast to phosphine-mono(diethyl phosphonate) catalysts 3a-3c, 3d yields a polymer with 87% internal olefins. <sup>13</sup>C NMR analysis shows that 2-olefins are the most common unsaturation (53%, E:Z approximately 1:1); 1-olefins (13%) and 3+-olefins (34%) were also identified. When an ethylene polymerization by 3d was conducted in the presence of 1-heptene, the heptene was not isomerized, which implies that the internal olefins are formed during chain growth rather than by isomerization of  $\alpha$ olefins released by chain transfer. <sup>13</sup>C NMR analysis also revealed that the PE produced by **3d** is highly linear (less than 1 branch per 1000 C), with only methyl branches detected. The

Figure 6. <sup>1</sup>H NMR spectra ( $CDCl_2CDCl_2$ , 100 °C) of ethylene/methyl acrylate copolymer produced by catalysts 3b (a) and 3d (b). See the Supporting Information for additional assignments.

 $T_{\rm m}$  value is consistent with linear PE of the observed molecular weight.  $^{27}$ 

The difference in the structures of the PEs produced by 3a,3b (>92%  $\alpha$ -olefin) and 3d (>87% internal olefins) provides insight into differences in the reactivities of the growing metal alkyl species in these catalysts. For 3a,3b, chain growth and chain transfer are fast, and either chain walking is not competitive with growth or the catalyst does not insert ethylene or undergo chain transfer from an internal alkyl position so that linear  $\alpha$ -olefins are formed. 3d also exhibits fast chain growth and fast chain transfer, but the predominance of internal unsaturation and the absence of branching indicate that chain walking does occur, and the resulting secondary alkyl species undergo chain transfer preferentially to chain growth.

Ethylene/Methyl Acrylate Copolymerizations. Catalysts 3b and 3d both incorporate methyl acrylate in ethylene copolymerizations, but with marked differences in the copolymer structure (Table 2). With both catalysts, at 28 atm ethylene, 1.50 M methyl acrylate, and 80 °C, the polymerization activity and product molecular weight are decreased relative to results for ethylene homopolymerization. Under these conditions, 3b incorporates 1.5 mol % methyl acrylate,<sup>29</sup> and notably, the methyl acrylate is selectively (95%) incorporated in-chain, with only 5% terminating chain-end placements observed (Figure 6a). Only 5% of terminating end groups contain MA, suggesting that, after acrylate insertion, chain growth is highly favored over chain transfer. 3d exhibits higher activity and acrylate incorporation  $(2.6 \text{ mol } \%)^{30}$  but is much less selective than 3b for in-chain acrylate placement, with only 60% incorporated in-chain and 40% incorporated into terminating chain-end groups (Figure 6b). This result indicates that, after acrylate insertion, 3d can undergo either chain growth or chain transfer with approximately equal probability.

The ability of these phosphine-diethyl phosphonate- and phosphine-bis(diethyl phosphonate)-based catalysts to incorporate methyl acrylate is a major difference from analogous phosphine-phosphine oxide complexes, which yielded no polymer in attempted ethylene/methyl acrylate copolymerizations.<sup>15</sup>

**Ethylene/Acrylic Acid Copolymerizations.** Both 3b and 3d copolymerize ethylene with acrylic acid (Table 2, entries 3 and 4). However, at 80 °C, 28 atm ethylene, and 0.75 M acrylic acid, the activity of both catalysts is severely depressed relative to ethylene homopolymerization. The small amount of polymer obtained with 3b is highly contaminated with Pd black and contains 0.45 mol % acrylic acid. The molecular weight (900 Da) is substantially lower than that obtained in ethylene homopolymerization. 3d yields copolymer containing approximately 1 mol % acrylic acid, with ca. 55% incorporated at chain ends (entry 4). Interestingly, the molecular weight of the ethylene/acrylic acid copolymer (1450 Da) is close to the value observed for ethylene homopolymerization.

#### CONCLUSIONS

Cationic phosphine-diethyl phosphonate complexes of the type (P-PO)PdMe(lutidine)<sup>+</sup> polymerize ethylene to low-molecularweight linear PE and copolymerize ethylene with methyl acrylate and acrylic acid. The polymerization activities of these catalysts vary widely with the substituents on the ancillary ligand. In ethylene/methyl acrylate copolymerizations, catalyst **3b** is highly selective for in-chain acrylate incorporation. Catalyst **3d** has a higher copolymerization activity and higher acrylate incorporation, but only 60% of the functionality is incorporated in-chain, with the remaining 40% as chain-end groups.

#### EXPERIMENTAL SECTION

**General Procedures.** All experiments were performed under a nitrogen atmosphere using drybox or Schlenk techniques. Nitrogen was purified by passage through columns containing Q-5 oxygen scavenger and activated molecular sieves. Methylene chloride, diethyl ether, and THF were dried by passage through columns containing activated alumina. Pentane was purified by passage through columns of BASF R3-11 oxygen scavenger and activated alumina. Compounds 1a,

**1b**,<sup>20</sup> (COD)PdMeCl,<sup>31</sup> (TMEDA)PdMe<sub>2</sub>,<sup>32</sup> and bis(diethylamino)chlorophosphine<sup>33</sup> were prepared by literature procedures. The following materials were obtained from commercial sources and used without further purification: PPh<sub>3</sub> (Aldrich, 99%), Pd(OAc)<sub>2</sub> (Aldrich, 99%), ethanol (Aldrich, anhydrous), 3-bromo-4-iodotoluene (Oakwood, 98%), NEt<sub>3</sub> (Aldrich, 99.5%), "BuLi solution (Aldrich, 1.6 M in hexanes), AgSbF<sub>6</sub> (Strem, 98%), 2,6-lutidine (Aldrich, 99+%), 4bromotoluene (Aldrich, 98%), HCl solution (Aldrich, 2.0 M in Et<sub>2</sub>O), butylated hydroxytoluene (BHT, Aldrich, 99%), and ethylene (Matheson, polymer grade). Chlorodiisopropylphosphine (Aldrich) was distilled prior to use. Acrylic acid (Aldrich) and methyl acrylate (Aldrich) were dried over MgSO<sub>4</sub> or CaCl<sub>2</sub>, respectively, distilled under reduced pressure, and stored at -40 °C. 1-Heptene (Aldrich) was dried over Na/benzophenone, transferred under reduced pressure, and stored in the dark.

Polymerization reactions were performed in a Parr 300 mL stainless steel autoclave, which was equipped with a mechanical stirrer, thermocouple, and water cooling loop and controlled by a Parr 4842 controller.

Elemental analyses were performed by Robertson Microlit Laboratories. Trace levels of solvents in elemental analysis samples were quantified by <sup>1</sup>H NMR. NMR spectra were acquired on Bruker DMX-500 or DRX-400 spectrometers at ambient temperatures unless otherwise indicated. <sup>1</sup>H and <sup>13</sup>C chemical shifts are reported relative to SiMe<sub>4</sub> and are internally referenced to residual <sup>1</sup>H and <sup>13</sup>C solvent resonances. <sup>31</sup>P chemical shifts are reported relative to externally referenced 85% H<sub>3</sub>PO<sub>4</sub>. <sup>19</sup>F chemical shifts are reported relative to CFCl<sub>3</sub>. Coupling constants are reported in Hz. NMR signals for ligands and complexes are assigned based on COSY, HMQC, HMBC, and <sup>1</sup>H{<sup>31</sup>P} experiments, as well as trends in chemical shifts and coupling constants derived from these experiments. <sup>13</sup>C and <sup>1</sup>H labeling schemes are provided in the Supporting Information. <sup>1</sup>H NMR integrals are fully consistent with these assignments. NMR assignments for polymers and copolymers are based on literature sources.<sup>2a,3a,4d,e,34</sup> Mass spectrometry was performed on an Agilent 6224 TOF-MS instrument (high resolution) or an Agilent 6130 LC-MS (low resolution).

Gel permeation chromatography (GPC) data were obtained on a Polymer Laboratories PL-GPC 200 instrument at 150 °C with 1,2,4trichlorobenzene (stabilized with 125 ppm BHT) as the mobile phase. Three PLgel 10  $\mu$ m Mixed-B LS columns were used. Molecular weights were calibrated using narrow polystyrene standards (ten-point calibration with  $M_n$  from 570 Da to 5670 kDa) and are corrected for linear polyethylene by universal calibration using the following Mark– Houwink parameters: polystyrene,  $K = 1.75 \times 10^{-2}$  cm<sup>3</sup> g<sup>-1</sup>,  $\alpha = 0.67$ ; polyethylene,  $K = 5.90 \times 10^{-2}$  cm<sup>3</sup> g<sup>-1</sup>,  $\alpha = 0.69$ .

**2a.** A flask was charged with **1a** (0.200 g, 50.3 mmol), (COD)PdMeCl (0.133 g, 50.2 mmol), and CH<sub>2</sub>Cl<sub>2</sub> (10 mL). The mixture was stirred at room temperature for 4 h. Removal of the solvent under vacuum afforded **2a** as an off-white solid (0.278 g, 99%). <sup>31</sup>P{<sup>1</sup>H} NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  31.6 (d,  $J_{PP}$  = 14, Pd-*P*), 19.9 (d,  $J_{PP}$  = 13, *P*==O). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  7.80 (m, 1H), 7.60–7.40 (m, 12 H), 7.18 (m, 1H), 4.00 (m, 2H, -OCH<sub>2</sub>CH<sub>3</sub>), 1.14 (t, 3H,  $J_{HH}$  = 7, -OCHH<sub>2</sub>CH<sub>3</sub>), 0.57 (d, 3H,  $J_{PH}$  = 4, Pd-CH<sub>3</sub>).

**2b.** A flask was charged with **1b** (0.503 g, 1.10 mmol), (COD)PdMeCl (0.277 g, 1.05 mmol), and CH<sub>2</sub>Cl<sub>2</sub> (12 mL). The pale yellow solution was stirred for 1 h at room temperature. The volatiles were removed under vacuum, yielding a yellow solid. The solid was dissolved in minimal CH<sub>2</sub>Cl<sub>2</sub> (approximately 3 mL). A portion of this solution was used to grow X-ray quality crystals via vapor diffusion of Et<sub>2</sub>O. The remaining fraction was layered with pentane and stored at -40 °C, yielding a white solid after 2 days. The solid was collected, rinsed with pentane and Et<sub>2</sub>O, and dried under high vacuum for 2 h. Yield 0.465 g (72%) of **2b** as an off-white solid. <sup>31</sup>P{<sup>1</sup>H}NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  24.1 (d, *J*<sub>PP</sub> = 11, Pd-*P*), 20.6 (d, *J*<sub>PP</sub> = 11, *P*=-O). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  7.79 (dddd, *J*<sub>PH</sub> = 13, 4, *J*<sub>HH</sub> = 8, 1, H<sub>a</sub>), 7.54 (m, H<sub>b</sub>), 7.53 (t, *J*<sub>HH</sub> = 7, H<sub>i</sub>), 7.52–7.42 (br, H<sub>k</sub>), 7.46 (td, *J*<sub>IHH</sub> = 7, 1, H<sub>c</sub>), 7.34 (m, H<sub>d</sub>), 7.01 (t, *J*<sub>HH</sub> = 8, H<sub>j</sub>), 6.96 (dd, *J*<sub>HH</sub> = 8, *J*<sub>PH</sub> = 5, H<sub>h</sub>), 4.13–3.93 (m, -OCHH<sub>2</sub>CH<sub>3</sub>), 3.62 (s, H<sub>m</sub>), 1.18 (t, *J*<sub>IHH</sub> = 7, -OCHH<sub>2</sub>CH<sub>3</sub>), 0.41 (d, *J*<sub>PH</sub> = 4, Pd-CH<sub>3</sub>). <sup>13</sup>C{<sup>1</sup>H</sup>} NMR (CD<sub>2</sub>Cl<sub>2</sub>):

δ 161.0 (d,  $J_{PC}$  = 3,  $C_L$ ), 137.1 (br d,  $J_{PC}$  = 11,  $C_K$ ), 136.8 (dd,  $J_{PC}$  = 44, 13,  $C_E$ ), 135.2 (dd,  $J_{PC}$  = 15, 2,  $C_D$ ), 133.6 (d,  $J_{PC}$  = 2,  $C_I$ ), 133.5 (dd,  $J_{PC}$  = 10, 8,  $C_A$ ), 131.6 (dd,  $J_{PC}$  = 7, 3,  $C_C$ ), 130.9 (dd,  $J_{PC}$  = 185, 18,  $C_F$ ), 130.1 (dd,  $J_{PC}$  = 13, 2,  $C_B$ ), 121.2 (d,  $J_{PC}$  = 11,  $C_J$ ), 116.5 (d,  $J_{PC}$  = 52,  $C_G$ ), 111.7 (d,  $J_{PC}$  = 4,  $C_H$ ), 64.3 (d,  $J_{PC}$  = 6,  $-OCH_2CH_3$ ), 55.6 (s,  $C_M$ ), 16.2 (d,  $J_{PC}$  = 7,  $-OCHH_2CH_3$ ), -1.3 (d,  $J_{PC}$  = 2, Pd-CH<sub>3</sub>). HRMS (m/z): Calcd for  $[C_{25}H_{31}P_2O_5PdCl + Na]^+$ : 637.0266, Found: 637.0273.

**3a.** A vial was charged with **2a** (0.113 g, 0.204 mmol), 2,6-lutidine (0.077 g, 0.72 mmol), and CH<sub>2</sub>Cl<sub>2</sub> (10 mL). The resulting solution was added to a second vial containing AgSbF<sub>6</sub> (0.070 g, 0.20 mmol). The resulting suspension was stirred rapidly for 1 h at room temperature, filtered through Celite, concentrated to ca. 1 mL, layered with pentane (ca. 5 mL), and allowed to stand at -40 °C overnight. The resulting white solid was collected by filtration, washed with pentane (4 × 2.5 mL), and dried. Yield 0.138 g, 70%. X-ray quality crystals were grown by layering pentane onto a CH<sub>2</sub>Cl<sub>2</sub> solution of **3a** and stored at -40 °C. <sup>31</sup>P{<sup>1</sup>H} NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  30.2 (d, *J*<sub>PP</sub> = 16, Pd-P), 19.6 (d, *J*<sub>PP</sub> = 16, *P*==O). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  7.76–7.20 (m, 17H), 3.87–3.81 (m, 2H, -OCH<sub>2</sub>CH<sub>3</sub>), 3.75–3.70 (m, 2H, -OCH<sub>2</sub>CH<sub>3</sub>), 3.10 (s, 6H, Lut-CH<sub>3</sub>), 1.02 (t, 3H, *J*<sub>HH</sub> = 7, -OCHH<sub>2</sub>CH<sub>3</sub>), 0.34 (d, *J*<sub>PH</sub> = 4, Pd-CH<sub>3</sub>). ESI-MS (CH<sub>2</sub>Cl<sub>2</sub>, positive ion), *m/z*: 626.1 [M]+.

**3b.** A vial was charged with **2b** (0.390 g, 0.634 mmol), AgSbF<sub>6</sub> (0.219, 0.637 mmol), and 2,6-lutidine (75 µL, 0.643 mmol). CH<sub>2</sub>Cl<sub>2</sub> (10 mL) was added, yielding a suspension of a white solid in a yellow supernatant, which was stirred at ambient temperature in the dark for 1 h. The mixture was filtered through Celite, and the volatiles were removed under vacuum, yielding 3b as a fine yellow powder (0.577 g, 98%). This material was rinsed with Et<sub>2</sub>O and placed under high vacuum for 18 h. <sup>1</sup>H NMR indicated the presence of 0.015 equiv of  $CH_2Cl_2$  and 0.113 equiv of  $Et_2O$ . X-ray quality crystals were grown by layering a  $CH_2Cl_2$  solution with  $Et_2O$ . <sup>31</sup>P{<sup>1</sup>H} NMR ( $CD_2Cl_2$ ):  $\delta$ 21.8 (d,  $J_{PP} = 16$ , P-Pd), 20.8 (d,  $J_{PP} = 15$ , P=O). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  7.85 (dddd,  $J_{\rm PH}$  = 14, 4,  $J_{\rm HH}$  = 8, 1,  $H_{\rm a}$ ), 7.72 (t,  $J_{\rm HH}$  = 8,  $H_{\rm o}$ ), 7.65 (m, H<sub>b</sub>), 7.62 (t,  $J_{HH} = 9$ , H<sub>i</sub>), 7.59 (t,  $J_{HH} = 8$ , H<sub>c</sub>), 7.43 (dd,  $J_{PH} = 18$ ,  $J_{\rm HH} = 8, H_{\rm d}$ , 7.40 (m, H<sub>k</sub>), 7.26 (d,  $J_{\rm HH} = 8, H_{\rm n}$ ), 7.07 (t,  $J_{\rm HH} = 8, H_{\rm i}$ ), 7.05 (dd,  $J_{HH} = 8$ ,  $J_{PH} = 5$ ,  $H_h$ ), 3.85–3.65 (m, –OCH $H_2$ CH<sub>3</sub>), 3.69  $(s, H_q), 3.09 (s, H_p), 1.05 (t, J_{HH} = 7, -OCHH_2CH_3), 0.17 (d, J_{PH} = 4,$ Pd-CH<sub>3</sub>). <sup>13</sup>C NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  161.0 (d,  $J_{PC}$  = 3, C<sub>L</sub>), 158.8 (d,  $J_{PC}$ = 1,  $C_{\rm M}$ ), 139.3 (s,  $C_{\rm O}$ ), 136.8 (d,  $J_{\rm PC}$  = 11,  $C_{\rm K}$ ), 135.7 (dd,  $J_{\rm PC}$  = 14, 3,  $C_D$ ), 135.2 (dd,  $J_{PC}$  = 46, 11,  $C_E$ ), 134.5 (d,  $J_{PC}$  = 2,  $C_I$ ), 133.8 (dd,  $J_{PC}$ = 10, 8,  $C_A$ ), 132.5 (dd,  $J_{PC}$  = 7, 3,  $C_C$ ), 130.8 (dd,  $J_{PC}$  = 14, 2,  $C_B$ ), 129.5 (dd,  $J_{PC}$  = 185, 18,  $C_F$ ), 123.2 (d,  $J_{PC}$  = 3,  $C_N$ ), 121.4 (d,  $J_{PC}$  = 11,  $C_I$ ), 114.7 (d,  $J_{PC}$  = 55,  $C_G$ ), 111.8 (d,  $J_{PC}$  = 5,  $C_H$ ), 64.5 (d,  $J_{PC}$  = 7,  $-OCH_2CH_3$ ), 55.6 (s,  $C_Q$ ), 26.4 (s,  $C_P$ ), 15.9 (d,  $J_{PC} = 6$ ,  $-\text{OCHH}_2\text{CH}_3$ ), -1.4 (t,  $J_{\text{PC}} = 2$ , Pd-CH<sub>3</sub>). Diethyl (2-Bromo-4-tolyl)phosphonate (5). A 1 L Schlenk flask was charged with triphenylphosphine (6.78 g, 25.9 mmol) and Pd(OAc)<sub>2</sub> (0.573 g, 2.55 mmol). Ethanol (330 mL), 3-bromo-4iodotoluene (25.6 g, 86.1 mmol), diethyl phosphite (58.7 g, 425 mmol), and triethylamine (73.8 mL, 530 mol) were added in the order listed. The resulting suspension of a white solid in a yellow supernatant was stirred and heated at reflux at 50 h; the mixture became homogeneous upon warming. The reaction mixture was added to a separatory funnel with 1 M HCl (aq) (190 mL) and diethyl ether (800 mL). The aqueous layer was extracted with Et<sub>2</sub>O (200 mL, 160 mL, 160 mL). The combined organic layer was washed with 2.5 M NaOH (aq) (90 mL), washed with brine (45 mL), and dried over MgSO<sub>4</sub>. Removal of solvent under reduced pressure yielded a mixture of 5, triphenylphosphine, and diethyl phosphite. 5 was purified by silica gel chromatography, using a 70:29:1 hexanes:acetone:triethylamine mixture as eluent. 5 was isolated as a pale yellow oil (13.9 g, 53% yield).  ${}^{31}P{}^{1}H$  NMR (CDCl<sub>3</sub>):  $\delta$  16.0.  ${}^{1}H$  NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  7.89  $(dd, J_{HH} = 8, J_{PH} = 14, H_a), 7.49 (d, J_{PH} = 5, H_d), 7.19 (d, J_{HH} = 8, H_b), \\ 4.25-4 (m, -OCHH_2CH_3), 2.36 (s, Ar-CH_3), 1.34 (t, J_{HH} = 7, \\$  $-OCHH_2CH_3$ ). <sup>13</sup>C{<sup>1</sup>H} NMR (CDCl<sub>3</sub>):  $\delta$  144.6 (d,  $J_{PC} = 3$ , C<sub>C</sub>),

1-Diethylphosphonato-2-diisopropylphosphinobenzene (1c). A 100 mL Schlenk flask was charged with 5 (1.00 g, 3.25 mmol) and THF (20 mL) and cooled to -78 °C. "BuLi solution (1.6 M, 2.05 mL, 3.28 mmol) was added via syringe, yielding an orange solution that was stirred for 1 h. A solution of chlorodiisopropylphosphine (0.530 g, 3.47 mmol) in THF (5 mL) was added via syringe, causing the orange color to fade. The flask was kept cold for at least 5 h and was then allowed to warm slowly overnight. The solvent was removed under reduced pressure, yielding a thick mixture of 1c and LiCl. 25 mL of CH<sub>2</sub>Cl<sub>2</sub> was added, and the resulting white suspension was filtered through Celite, yielding a clear solution. The solvent was removed under reduced pressure, yielding 1c as an oxidatively sensitive, waxy white solid (1.02 g, 91%) after several hours.  ${}^{31}P{}^{1}H{}^{NMR}$  (CD<sub>2</sub>Cl<sub>2</sub>): δ 19.1 (s, P=O), 3.2 (s, P). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>): δ 7.86 (ddd,  $J_{PH}$  = 13,  $J_{\rm HH}$  = 8,  $J_{\rm PH}$  = 3,  $H_{\rm a}$ ), 7.46 (dd,  $J_{\rm PH}$  = 2.3, 2.2,  $H_{\rm d}$ ), 7.22 (ddd,  $J_{\rm HH}$  = 8,  $J_{\rm PH} = 2$ , 1,  $H_{\rm b}$ ), 4.12 (m,  $-\text{OCH}H_2\text{CH}_3$ ), 2.09 (sept. of d,  $J_{\rm HH} = 7$ ,  $J_{\rm PH} = 4$ , P-CH(CH<sub>3</sub>)<sub>2</sub>, 1.32 (t,  $J_{\rm HH} = 7$ , -OCHH<sub>2</sub>CH<sub>3</sub>), 1.15 (dd,  $J_{\rm PH} =$ 14,  $J_{\text{HH}} = 7$ , P-CH(CH<sub>3</sub>)<sub>2</sub>), 0.88 (dd,  $J_{\text{PH}} = 13$ ,  $J_{\text{HH}} = 7$ , P-CH(CH<sub>3</sub>)<sub>2</sub>). <sup>13</sup>C{<sup>1</sup>H} NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  143.9 (dd,  $J_{PC}$  = 29, 15, C<sub>E</sub>), 142.9 (d,  $J_{PC}$  $= 3, C_{\rm C}$ ), 135.2 (dd,  $J_{\rm PC} = 17, 3, C_{\rm D}$ ), 135.1 (dd,  $J_{\rm PC} = 11, 9, C_{\rm A}$ ), 134.6  $(dd, J_{PC} = 191, 32, C_F)$ , 130.3  $(dd, J_{PC} = 15, 1, C_B)$ , 63.1  $(dd, J_{PC} = 6, 1)$ 3,  $-OCH_2CH_3$ ), 27.1 (d,  $J_{PC} = 15$ , P-CH(CH<sub>3</sub>)<sub>2</sub>), 22.6 (d,  $J_{PC} = 2$ ,  $C_G$ ), 21.6 (d,  $J_{PC} = 13$ , P-CH(CH<sub>3</sub>)<sub>2</sub>), 21.4 (d,  $J_{PC} = 20$ , P-CH(CH<sub>3</sub>)<sub>2</sub>, 17.6 (d,  $J_{PC} = 7$ , -OCHH<sub>2</sub>CH<sub>3</sub>). 2c. A vial was charged with 1c (0.300 g, 0.870 mmol), (COD)PdMeCl (0.223 g, 0.841 mmol), and CH<sub>2</sub>Cl<sub>2</sub> (8 mL). The resulting yellow solution was stirred for 1 h at room temperature and then filtered through Celite. Removal of the solvent under vacuum yielded a yellow solid, which was dissolved in 3 mL of CH<sub>2</sub>Cl<sub>2</sub>. Several small portions of this solution were used in attempted crystallizations; most of the solution was placed in a vial and layered with pentane. After several days at -40 °C, X-ray quality crystals of 2c had formed in the vial (structure shown in the Supporting Information). These were collected on a frit, yielding 2c as a pale yellow powder (0.152 g, 36%). This material was found to contain 0.33 equiv of CH<sub>2</sub>Cl<sub>2</sub> by <sup>1</sup>H NMR. <sup>31</sup>P{<sup>1</sup>H}NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  41.6 (d, 13; *P*-Pd), 21.8 (d, 14; *P*=O). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  7.74 (ddd,  $J_{\rm HH}$  = 8,  $J_{\rm PH}$  = 8, 3, H<sub>a</sub>), 7.54 (t,  $J_{\rm PH}$  = 6,  $H_d$ ), 7.44 (d,  $J_{HH}$  = 7,  $H_b$ ), 4.35 (m, -OCH $H_2$ CH<sub>3</sub>), 2.54 (sept.,  $J_{HH}$  = 7,  $-CH(CH_3)_2$ ), 2.46 (s, H<sub>g</sub>), 1.39 (t,  $J_{HH} = 7$ ,  $-OCHH_2CH_3$ ), 1.20  $(dd, J_{HH} = 7, J_{PH} = 15, -CH(CH_3)_2), 1.17(dd, J_{HH} = 7, J_{HP} = 18, -CH(CH_3)_2)$  $-CH(CH_3)_2$ , 0.74 (d,  $J_{PH} = 3$ , Pd- $CH_3$ ). <sup>13</sup>C{<sup>1</sup>H} NMR ( $CD_2Cl_2$ ):  $\delta$ 143.4 (dd,  $J_{PC} = 5,3, C_C$ ), 134.1 (d,  $J_{PC} = 16, C_D$ ), 133.5 (t,  $J_{PC} = 9$ ,  $C_A$ ), 132.8 (dd,  $J_{PC}$  = 29, 13,  $C_E$ ), 131.7 (dd,  $J_{PC}$  = 14, 2,  $C_B$ ), 130.2  $(dd, J_{PC} = 194, 13, C_F), 64.6 (d, J_{PC} = 6, -OCH_2CH_3), 25.7 (d, J_{PC} = 6)$ 26, P-CH(CH<sub>3</sub>)<sub>2</sub>), 21.9 (d,  $J_{PC}$  = 1, C<sub>G</sub>), 19.0 (d,  $J_{PC}$  = 5, P-CH(CH<sub>3</sub>)<sub>2</sub>), 18.5 (s, P-CH(CH<sub>3</sub>)<sub>2</sub>), 16.3 (d,  $J_{PC}$  = 7, -OCHH<sub>2</sub>CH<sub>3</sub>), -6.3 (d,  $J_{PC}$  = 2, Pd-CH<sub>3</sub>). EA: calcd for C<sub>18</sub>H<sub>33</sub>P<sub>2</sub>O<sub>3</sub>PdCl·0.33 CH2Cl2, %: C, 41.59; H, 6.40. Found: C, 41.35; H, 6.18.

**3c.** A vial was charged with **2c** (0.129 g, 0.256 mmol), AgSbF<sub>6</sub> (0.088 g, 0.255 mmol), 2,6-lutidine (30  $\mu$ L, 0.258 mmol), and CH<sub>2</sub>Cl<sub>2</sub> (5 mL). The resulting yellow solution was stirred for 40 min at room temperature. Filtration through Celite yielded a clear yellow solution. The solvent was removed under vacuum, yielding **3c** as a yellow solid (0.188 g, 91%, crude), which was purified by layering Et<sub>2</sub>O onto a THF solution of **3c** and storing at -40 °C for 2 days. The resulting microcrystalline solid was collected on a frit, rinsed with Et<sub>2</sub>O, and dried under high vacuum for 18 h. **3c** was found to contain 0.03 equiv of CH<sub>2</sub>Cl<sub>2</sub> by <sup>1</sup>H NMR. X-ray quality crystals were grown by vapor diffusion of diethyl ether into a THF solution of **3c**. <sup>31</sup>P{<sup>1</sup>H} NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  41.3 (d,  $J_{PP} = 14$ , *P*-Pd), 20.1 (d,  $J_{PP} = 15$ , *P*=O). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  7.78 (ddd,  $J_{HH} = 8$ ,  $J_{HP} = 8$ , 4, H<sub>a</sub>), 7.72 (t,  $J_{HH} = 8$ , H<sub>f</sub>), 7.65 (t,  $J_{HP} = 7$ , H<sub>c</sub>), 7.54 (dd,  $J_{HH} = 8$ ,  $J_{PH} = 1$ , H<sub>b</sub>), 7.25 (d,  $J_{HH} = 8$ , H<sub>e</sub>), 4.06-3.92 (m, -OCHH<sub>2</sub>CH<sub>3</sub>), 3.09 (s, H<sub>b</sub>), 2.65 (sept d,  $J_{HH}$

1d. A 500 mL Schlenk flask was charged with 5 (12.02 g, 39.14 mmol) and THF (300 mL). The flask was cooled to -78 °C, and "BuLi solution (1.6 M, 26.3 mL, 42.1 mmol) was added via syringe, resulting in a deep orange-brown solution that was stirred for 20 min. A solution of 7 (4.569 g, 19.4 mmol) in THF (20 mL) was added by syringe, yielding a pale orange solution. After stirring for 40 min, the cold bath was removed, and the flask was allowed to warm to room temperature overnight, with stirring. The reaction mixture was then concentrated under reduced pressure to an orange oil, which was added to a separatory funnel with  $Et_2O$  (300 mL) and  $H_2O$  (300 mL). The aqueous layer was extracted with  $3 \times 100$  mL of Et<sub>2</sub>O. The combined organic layer was dried over MgSO4, and the solvent was removed under reduced pressure to yield a viscous yellow oil. The crude product was loaded onto silica gel packed in ethyl acetate, and ethyl acetate was run through the column to remove impurities. 1d was then eluted with a 1:11 methanol:ethyl acetate mixture. Removal of solvent under reduced pressure yielded a thick, cloudy oil. Heating at 80 °C for 7 h yielded 1d as a white solid (5.32 g, 44%).  $^{31}P\{^{1}H\}$ NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  18.7 (s, P=O), -9.9 (s, P). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$ 7.94 (ddd,  $J_{\rm PH} = 4$ ,  $J_{\rm HH} = 8$ ,  $J_{\rm PH} = 14$ ,  $H_{\rm a}$ ), 7.33 (dd,  $J_{\rm HH} = 9$ ,  $J_{\rm PH} = 1$ ,  $H_{e}$ ), 7.23 (d,  $J_{HH} = 7$ ,  $H_{b}$ ), 7.03 (t,  $J_{PH} = J_{HH} = 8$ ,  $H_{d}$ ), 6.71 (s,  $H_{c}$ ), 4.1–3.7 (m,  $-\text{OCHH}_2\text{CH}_3$ ), 2.20 (s, H<sub>j</sub>), 1.30 (s, H<sub>i</sub>), 1.09 (t,  $J_{\text{HH}} = 7$ ,  $-\text{OCHH}_2\text{CH}_3$ ), 1.07 (t,  $J_{\text{HH}} = 7$ ,  $-\text{OCHH}_2\text{CH}_3$ ). <sup>13</sup>C{<sup>1</sup>H} NMR  $(CD_2Cl_2)$ :  $\delta$  151.9 (s,  $C_Q$ ), 142.5 (d,  $J_{PC}$  = 3,  $C_P$ ), 142.5 (dd,  $J_{PC}$  = 27, 14,  $C_M$ ), 136.6 (d,  $J_{CP}$  = 16,  $C_C$ ), 135.3 (d,  $J_{CP}$  = 12,  $C_O$ ), 135.2 (dd,  $J_{\rm PC} = 8, 11, C_{\rm A}$ ), 134.2 (d,  $J_{\rm CP} = 21, C_{\rm D}$ ), 131.1 (dd,  $J_{\rm PC} = 188, 31, C_{\rm N}$ ), 129.0 (d,  $J_{PC} = 15$ ,  $C_B$ ), 125.6 (d,  $J_{PC} = 7$ ,  $C_E$ ), 62.12 (dd,  $J_{PC} = 6$ , 2,  $-OCH_2CH_3$ ), 62.07 (dd,  $J_{PC} = 6, 2, -OCH_2CH_3$ ), 34.9 (s,  $C_L$ ), 31.4 (s,  $C_I$ ), 21.7 (d,  $J_{PC} = 2$ ,  $C_I$ ), 16.29 (d,  $J_{PC} = 7$ ,  $-OCHH_2CH_3$ ), 16.26 (d,  $J_{PC} = 7$ ,  $-OCHH_2CH_3$ ). ESI-MS (1:1 CH<sub>2</sub>Cl<sub>2</sub>:MeOH, positive ion, fragmentor 40), m/z: 845.3 [M - SbF<sub>6</sub> - H], 738.1 [M - SbF<sub>6</sub> - lut - H]. EA: Calcd for C<sub>40</sub>H<sub>57</sub>P<sub>3</sub>O<sub>6</sub>NPdSbF<sub>6</sub>, %: C, 44.36; H, 5.31; N, 1.29. Found: C, 44.09; H, 5.15; N, 1.36.

**Ethylene Homopolymerizations.** In a glovebox, a 200 mL glass autoclave liner was charged with a solution of the catalyst in  $CH_2Cl_2$  (ca. 1 mL). The solvent was removed under vacuum, and toluene (50 mL) was added. For catalyst loadings larger than 5  $\mu$ mol, the catalyst was weighed directly into the liner. The glass liner was placed in a stainless steel autoclave, which was sealed and removed from the glovebox. The autoclave was heated to (typically) 80 °C and pressurized with ethylene while the contents were stirred. After 2 h, the autoclave was cooled to 25 °C and vented. Acetone (50 mL) was added to precipitate polymer. The polymer was collected by filtration, rinsed with acetone, and dried overnight in a vacuum oven. The oligomer content of the filtrate was determined by GC–MS analysis.

**Ethylene Copolymerizations with Methyl Acrylate or Acrylic Acid.** In a glovebox, a 200 mL glass autoclave liner was charged with catalyst, toluene (50 mL), and, if applicable, BHT (0.100 g). Comonomer was added, and the liner was placed in a stainless steel autoclave, which was sealed and removed from the glovebox. Stirring was initiated, the autoclave was pressurized with ethylene (22 atm), and the ethylene line was closed. The autoclave was heated to 80 °C, and the pressure was adjusted to 28 atm with ethylene on demand. After the listed polymerization time, the autoclave was cooled and vented. MeOH (200 mL, methyl acrylate copolymerization) or 10% H<sub>2</sub>O/90% MeOH solution (200 mL, acrylic acid copolymerization) was added to precipitate the polymer. The solid was collected by filtration and washed with the corresponding solvent. For the acrylic acid copolymerization, the polymer was then washed with MeOH. All samples were then dried overnight in a vacuum oven.

#### ASSOCIATED CONTENT

#### Supporting Information

Crystal structure report for compounds 2g, 3c, 2c, 3b, and 3a; synthesis of compounds; NMR labeling scheme; molecular structure of complex 2c; ethylene homopolymerization data; Schulz–Flory analysis of oligomers from 3a; 1-heptene isomerization experiment; ethylene copolymerization data; variable-temperature NMR spectra of 3d; NMR spectra of compounds, oligomer fraction, and polymers; and crystallographic data in CIF format. This material is available free of charge via the Internet at http://pubs.acs.org.
