Syntheses, characterization and facial—meridional isomerism of tungsten tricarbonyl diphosphine complexes

DALTON FULL PAPER

Sodio C. N. Hsu and Wen-Yann Yeh*

Department of Chemistry, National Sun Yat-Sen University, Kaohsiung 80424, Taiwan

The complexes fac-[W(CO)₃(η^2 -dppf)(η^1 -dppf)] **4f**, fac-[W(CO)₃(η^2 -dppm)(η^1 -dppf)] **5f**, fac-[W(CO)₃(η^2 -dppf)-(η^1 -dppe)] **6f**, fac-[W(CO)₃(η^2 -dppe)(η^1 -dppf)] **7f**, fac-[W(CO)₃(η^2 -dppm)(η^1 -dppe)] **8f** and fac-[W(CO)₃(η^2 -dppe)-(η^1 -dppm)] **9f** have been prepared by treating fac-[W(CO)₃(η^2 -diphos)(NCMe)] **1–3** [diphos = 1,1'-bis(diphenyl-phosphino)ferrocene (dppf), dppm (Ph₂PCH₂PPh₂) or dppe (Ph₂PCH₂CH₂PPh₂)] with the corresponding diphosphines. The initially afforded facial isomers are converted into the meridional forms (**4m–9m**) in a subsequent, slow rearrangement process through opening of the chelated diphosphine ligand. A five-co-ordinate, square-pyramidal intermediate is presumed. In contrast, acid-assisted facial–meridional isomerization of **4f** and **6f** is likely via a seven-co-ordinate hydrido species. The new compounds have been characterized by elemental analyses and IR, mass and NMR spectroscopy.

The d⁶ metal tricarbonyl complexes, M(CO)₃L₃, exhibit facial (fac) and meridional (mer) isomers. 1-6 When L is a good σ donor and poor π acceptor relative to CO the fac isomer is expected to be more stable electronically to achieve stronger M to CO back donation. On the other hand, the mer isomer is less sterically encumbered and is favored when L contains bulky groups. Several studies regarding their isomerization have been reported. For example, Rousche and Dobson⁸ studied the thermolysis of fac-[Mo(CO)₃(η^2 -dppe){P(OPrⁱ)₃}] (dppe = Ph₂- $PCH_2CH_2PPh_2$) at 120 °C leading to mer-[Mo(CO)₃(η^2 -dppe)-{P(OPrⁱ)₃}] via dissociation/association of the P(OPrⁱ)₃ ligand. Darensbourg et al.9 observed that on prolonged standing a solution of fac-[W(CO)₃(13 CO)(η^{2} -dppm)] (dppm = Ph₂PCH₂-PPh₂) at room temperature afforded a mixture of facial and meridional isomers, presumably undergoing an intramolecular CO rearrangement process. Schenk and Hilpert 10 found an interesting reaction of fac-[Mo(CO)₃(η^2 -dppm)(NCMe)] and dppe giving fac-[Mo(CO)₃(η²-dppe)(η¹-dppm)] with switch of the chelate ligand, but no subsequent isomerization of this compound was indicated. In contrast, Krishnamurthy and coworkers 11 revealed that treating fac-[Mo(CO)₃(NCMe){η²-Ph₂- $\begin{array}{ll} PN(Pr^{i})PPh(dmpz)\}] & (dmpz=3,5-dimethylpyrazol-1-yl) & with \\ dppe & produced & \textit{fac-} & and & \textit{mer-}[Mo(CO)_{3}\{\eta^{2}-Ph_{2}PN(Pr^{i})-\eta^{2}-Ph_{2}PN(Pr^{i})-\eta^{2}-\eta^$ PPh(dmpz) $\{\eta^1-dppe\}$, in which the four-membered diphosphazane ring was retained and the dppe was co-ordinated in an η^1 fashion. In these reactions, however, a plausible isomerization mechanism involving opening the η^2 -diphosphine ring was ignored.

We recently prepared the complexes fac-[W(CO)₃(η^2 -dppf)-(PMe₃)] and fac-[W(CO)₃(η^2 -dppf)(PPh₂X)] [dppf = 1,1′-bis(diphenylphosphino)ferrocene, X = H or OH], which did not lead to the meridional isomers upon heating. ¹² Apparently their geometries are not sterically congested enough to surpass the electronic advantages. We then investigated the analogous complexes with bulky diphosphines. This paper presents results concerning the syntheses and facial–meridional isomerism of a series of complexes of the type [W(CO)₃(η^2 -diphos)-(η^1 -diphos')] (diphos = diphosphine). It appears that the chelated diphosphine ligand is opened up to facilitate the isomerization reaction.

Experimental

General methods

Reactions were performed on a double-manifold Schlenk line

under dried nitrogen. The complexes fac-[W(CO)₃(η^2 -dppf)-(NCMe)] ¹² 1 and fac-[W(CO)₃(η^2 -dppm)(NCMe)] ⁹ 2 were prepared by literature methods. 1,1'-Bis(diphenylphosphino)ferrocene (dppf) was prepared from ferrocene and chlorodiphenylphosphine as described.¹³ Trimethylphosphine (1.0 M in toluene), methyldiphenylphosphine, triphenylphosphine, dppm, dppe and tetrafluoroboric acid (54% in Et₂O) from Aldrich were used without further purification. Solvents were dried over appropriate agents under nitrogen and distilled before use. Thin-layer chromatographic (TLC) plates were prepared from silica gel (Merck). Infrared spectra were recorded with a 0.1 mm path CaF₂ solution cell on a Hitachi I-2001 spectrometer, ¹H and ³¹P NMR spectra on a Varian VXR-300 spectrometer at 300 and 121.4 MHz, respectively, and fast atom bombardment (FAB) mass spectra on a VG Blotch-5022 spectrometer. Elemental analyses were performed at the National Science Council Regional Instrumentation Center at the National Chung-Hsing University, Taichung, Taiwan.

Preparation of fac-[W(CO)₃(η²-dppe)(NCMe)] 3

The complex [W(CO)₃(NCMe)₃] (500 mg, 1.28 mmol) and dppe (510 mg, 1.28 mmol) were placed in a Schlenk flask (50 cm³) containing a magnetic stirring bar. The flask was capped with a rubber septum, evacuated and backfilled with nitrogen. After adding dichloromethane (15 cm³), the solution was stirred at ambient temperature for 5 h, forming a yellow precipitate. The supernatant was removed *via* a cannula and the solids washed with diethyl ether (50 cm³) and then dried under vacuum. The complex *fac*-[W(CO)₃(η^2 -dppe)(NCMe)] 3 was afforded in 86% yield (780 mg, 1.10 mmol). Mass spectrum (FAB): *mlz* 707 (M^+ , ¹⁸⁴W), 666 (M^+ – CH₃CN) and 666 – 28n (n = 1–3); IR (1,2-C₂H₄Cl₂, cm⁻¹): v(CO) 1932vs, 1838s and 1822s. ³¹P-{¹H} NMR (CD₂Cl₂, 20 °C): δ 46.25 (s; with ¹⁸³W satellites, ¹ J_{WP} = 226 Hz). ¹H NMR (CD₂Cl₂, 20 °C): δ 1.97 (s, 3 H, NCMe), 2.59 (m, 4 H, CH₂) and 7.30–7.80 (m, 20 H, Ph).

Reaction of complex 1 and dppm

The complex fac-[W(CO)₃(η^2 -dppf)(NCMe)] **1** (50 mg, 0.058 mmol) and dppm (25 mg, 0.065 mmol) were placed in a Schlenk flask (50 cm³) containing a magnetic stirring bar. The flask was fitted with a rubber septum, evacuated and backfilled with nitrogen. After adding dichloromethane (15 cm³), the solution was stirred at ambient temperature for 20 h. The mixture was dried under vacuum and the residue separated by TLC, eluting

with CH_2Cl_2-n -hexane (1:1, v/v). Three bands were obtained according to the order of appearance: yellow [W(CO)₄- $(\eta^2\text{-dppf})$] (trace amount), yellow $mer-[W(CO)_3(\eta^2\text{-dppm}) (\eta^1\text{-dppf})$] **5m** (28 mg, 40%) and yellow fac-[W(CO)₃($\eta^2\text{-dppf}$)- $(\eta^{1}\text{-dppm})$] **4f** (30 mg, 43%).

Complex 5m (Found: C, 61.23; H, 4.37. C₆₂H₅₀FeO₃P₄W requires C, 61.71; H, 4.18%): mass spectrum (FAB) m/z 1206 (M^{+}) ; IR $(1,2-C_2H_4Cl_2, cm^{-1})$ v(CO) 1966w, 1864s and 1838 (sh); ${}^{31}P-\{{}^{1}H\}$ NMR (CD₂Cl₂, 20 °C) δ -25.0 (dd, J_{PP} = 31 and 24; with 183 W satellites, $J_{\text{WP}} = 180$, dppm), -16.69 (s, dppf), -11.56 (dd, $J_{\text{PP}} = 31$ and 67; with 183 W satellites, $J_{\text{WP}} = 244$, dppm) and 22.96 (dd, $J_{PP} = 24$ and 67, with ¹⁸³W satellites, $J_{WP} = 302 \text{ Hz}, \text{ dppf}); {}^{1}\text{H NMR (CD}_{2}\text{Cl}_{2}, 20 {}^{\circ}\text{C}) \delta 3.75 \text{ (s, 2 H)},$ 4.00 (s, 2 H), 4.26 (s, 2 H), 4.30 (s, 2 H, C₅H₄), 5.04 (t, 2 H, $J_{PH} = 9 \text{ Hz}, \text{ CH}_2$) and 7.00–7.70 (m, 40 H, C₆H₅).

Complex 4f (Found: C, 61.50; H, 4.19. C₆₂H₅₀FeO₃P₄W requires C, 61.71; H, 4.18%): mass spectrum (FAB) m/z 1206 (M^+) , 822 $(M^+ - dppm)$ and 822 – 28n (n = 1-3); IR (1,2-1) $C_2H_4Cl_2$, cm⁻¹): v(CO) 1938s, 1842s and 1826 (sh); ³¹P-{¹H} NMR (CD₂Cl₂, 20 °C) δ -24.16 (d, J_{PP} = 23, dppm), 8.17 (dt, $J_{PP} = 23, 26$; with ¹⁸³W satellites, $J_{WP} = 214$, dppm) and 16.91 (d, $J_{PP} = 26$; with ¹⁸³W satellites, $J_{WP} = 230$ Hz, dppf); ¹H NMR (CD₂Cl₂, 20 °C) δ 3.08 (s, 2 H), 3.95 (s, 2 H), 4.27 (s, 2 H), 4.46 (s, 2 H, C₅H₄), 4.68 (s, 2 H, CH₂) and 6.90–7.50 (m, 40 H, C_6H_5).

Reaction of complex 2 and dppf

The complex fac-[W(CO)₃(η^2 -dppm)(NCMe)] **2** (20 mg, 0.023 mmol) and dppf (50 mg, 0.09 mmol) and CD₂Cl₂ (2 cm³) were placed in a dry NMR tube under nitrogen. The reaction was carried out at ambient temperature and monitored by ³¹P NMR spectroscopy. The resonances corresponding to fac-[W(CO)₃- $(\eta^2$ -dppm) $(\eta^1$ -dppf)] **5f** were detected initially. However, only 5m (17 mg, 0.014 mmol, 61%) was obtained after separation by TLC. Attempts to isolate 5f in pure form have been unsuccessful. Complex **5f**: ${}^{31}P-{}^{1}H$ } NMR (CD₂Cl₂, 20 °C) δ -22.46 (d, $J_{PP} = 22$, dppm), -17.03 (s, dppf) and 12.96 (t, $J_{PP} = 22$ Hz, dppf).

Reaction of complex 1 and dppe

The reaction of fac-[W(CO)₃(η^2 -dppf)(NCMe)] 1 (50 mg, 0.058 mmol) and dppe (25 mg, 0.063 mmol) was carried out (5 h) and worked up in a fashion similar to that of 1 and dppm. Three products were obtained in order of appearance on the TLC plate: yellow [W(CO)₄(η²-dppf)] (trace amount), yellow fac- $[W(CO)_3(\eta^2\text{-dppf})(\eta^1\text{-dppe})]$ 6f (38 mg, 54%) and yellow $fac, fac-[\{W(CO)_3(\eta^2-dppf)\}_2(\eta^1:\eta^1-dppe)]$ **6ff** (25 mg, 42%).

Complex **6f** (Found: C, 61.72; H, 4.39. C₆₃H₅₂FeO₃P₄W requires C, 61.99; H, 4.29%): mass spectrum (FAB) m/z 1220 (M^{+}) , 1220 – 28n (n = 1–3), 822 (M^{+} – dppe) and 822 – 28n (n = 1-3); IR $(1,2-C_2H_4Cl_2, cm^{-1})$ v(CO) 1938s, 1842s and 1826 (sh); ${}^{31}P-{}^{1}H$ } NMR (CD₂Cl₂, 20 °C) $\delta - 12.49$ (d, $J_{PP} = 31$, dppe), 9.14 (dt, $J_{PP} = 31$, 27; with ¹⁸³W satellites, $J_{WP} = 211$, dppe) and 16.0 (d, $J_{PP} = 27$; with ¹⁸³W satellites, $J_{WP} = 227$ Hz, dppf); ¹H NMR (CD₂Cl₂, 20 °C) δ 1.82 (m, 2 H), 2.35 (m, 2 H, C₂H₄), 3.91 (s, 2 H), 4.24 (s, 2 H), 4.45 (s, 2 H), 4.67 (s, 2 H, C_5H_4) and 6.90–7.50 (m, 40 H, C_6H_5).

Complex 6ff (Found: C, 58.92; H, 3.87. C₁₀₀H₈₀Fe₂O₆P₆W₂ requires C, 58.79; H, 3.95%): mass spectrum (FAB) m/z 1220 $[M^{+} - W(CO)_{3}(dppf)]$ and 822 $[M^{+} - W(CO)_{3}(dppf)(dppe)]$; IR $(1,2-C_2H_4Cl_2, \text{ cm}^{-1}) \text{ v(CO)}$ 1938s, 1842s and 1828 (sh); ³¹P-{¹H} NMR $(\text{CD}_2\text{Cl}_2, 20 \,^{\circ}\text{C}) \,\delta$ 15.0 (t, $J_{PP} = 27$; with ¹⁸³W satellites, $J_{WP} = 232$, dppe) and 17.33 (d, $J_{PP} = 27$; with ¹⁸³W satellites, $J_{WP} = 230 \text{ Hz}$, dppf); ¹H NMR (CD₂Cl₂, 20 °C) δ 2.48 (br, 4 H, C₂H₄), 3.97 (s, 4 H), 4.24 (s, 4 H), 4.49 (s, 4 H), 4.73 (s, 4 H, C_5H_4) and 6.80–7.50 (m, 60 H, C_6H_5).

Reaction of complex 3 and dppf

The complex fac-[W(CO)₃(η^2 -dppe)(NCMe)] 3 (100 mg, 0.141

mmol) was treated with dppf (80 mg, 0.14 mmol) by the same method as described above (60 h). Three products were isolated: yellow $[W(CO)_4(\eta^2\text{-dppe})]$ (32 mg, 33%), yellow mer- $[W(CO)_3(\eta^2\text{-dppe})(\eta^1\text{-dppf})]$ 7m (45 mg, 26%) and yellow fac-[W(CO)₃(η^2 -dppe)(η^1 -dppf)] **7f** (50 mg, 29%).

Complex 7m (Found: C, 61.82; H, 4.40. C₆₃H₅₂FeO₃P₄W requires C, 61.99; H, 4.29%): mass spectrum (FAB) m/z 1221 (M^+) and 1221 - 28n (n = 1-3); IR $(1,2-C_2H_4Cl_2, cm^{-1}) v(CO)$ 1965w and 1859s; ³¹P-{¹H} NMR (CD₂Cl₂, 20 °C) δ 47.10 (dd, $J_{\rm PP} = 12$, 69; with $^{183}{\rm W}$ satellites, $J_{\rm WP} = 271$, dppe), 38.79 (dd, $J_{\rm PP} = 15$, 12; with $^{183}{\rm W}$ satellites, $J_{\rm WP} = 216$, dppe), 18.32 (dd, $J_{PP} = 15$, 69; with ¹⁸³W satellites, $J_{WP} = 295$ Hz, dppf) and -17.03 (s, dppf); ¹H NMR (CD₂Cl₂, 20 °C) δ 2.38 (br, 4 H, C_2H_4), 3.71 (s, 2 H), 3.95 (s, 2 H), 4.17 (s, 2 H), 4.23 (s, 2 H, C_5H_4) and 6.90–7.70 (m, 40 H, C_6H_5).

Complex 7f (Found: C, 61.85; H, 4.22. C₆₃H₅₂FeO₃P₄W requires C, 61.99; H, 4.29%): mass spectrum (FAB) m/z 1221 (M^+) and 1221 - 28n (n = 1-3); IR $(1,2-C_2H_4Cl_2, cm^{-1})$ v(CO)1935s and 1840s; ³¹P-{¹H} NMR (CD₂Cl₂, 20 °C) δ 33.68 (d, $J_{PP} = 22$; with ¹⁸³W satellites, $J_{WP} = 220$, dppe), 8.02 (t, $J_{PP} = 22$; with 183 W satellites, $J_{WP} = 213$ Hz, dppf) and -17.26 (s, dppf); ¹H NMR (CD₂Cl₂, 20 °C) δ 2.48 (br, 4 H, C₂H₄), 3.83 (s, 2 H), 3.97 (s, 2 H), 4.27 (s, 2 H), 4.62 (s, 2 H, C_5H_4) and 6.60-7.70 (m, $40 \text{ H}, \text{C}_6\text{H}_5$).

Reaction of complex 2 and dppe

Complex fac-[W(CO)₃(η^2 -dppm)(NCMe)] 2 (100 mg, 0.144 mmol) was treated with dppe (60 mg, 0.15 mmol) for 50 h at 28 °C by the same method as described above. Yellow mer-[W(CO)₃(η^2 -dppe)(η^1 -dppm)] **9m** (70 mg, 46%) and yellow *fac*- $[W(CO)_3(\eta^2\text{-dppe})(\eta^1\text{-dppm})]$ 9f (58 mg, 38%) were obtained by TLC. Two intermediates corresponding to fac-[W(CO)₃(η^2 dppm)(η^1 -dppe)] **8f** and mer-[W(CO)₃(η^2 -dppm)(η^1 -dppe)] **8m** were detected by ³¹P NMR spectroscopy during the reaction. However, attempts to isolate them failed, leading only to 9m and 9f.

Complex 8f: ${}^{31}P-{}^{1}H$ } NMR (CD₂Cl₂, 20 °C) δ -21.85 (d, $J_{PP} = 22$, dppm), -12.53 (d, $J_{PP} = 36$, dppe) and 15.08 (dt, $J_{PP} = 22, 36 \text{ Hz, dppe}$).

Complex 8m: ${}^{31}P-{}^{1}H}$ NMR (CD₂Cl₂, 20 °C) δ -24.60 (dd, $J_{PP} = 23$, 30, dppm), -12.35 (dd, $J_{PP} = 30$, 66, dppm), -12.06 (d, $J_{PP} = 39$, dppe) and 25.67 (ddd, $J_{PP} = 23$, 39, 66 Hz, dppe).

Complex **9m** (Found: C, 61.67; H, 4.46. $C_{54}H_{46}O_3P_4W$ requires C, 61.73; H, 4.41%): mass spectrum (FAB) m/z 1050 (M^+) and 1050 - 28n (n = 1-3); IR $(1,2-C_2H_4Cl_2, cm^{-1}) v(CO)$ 1966w and 1860s; ³¹P-{¹H} NMR (CD₂Cl₂, 20 °C) δ 47.85 (dd, $J_{PP} = 11$, 69; with ¹⁸³W satellites, $J_{WP} = 273$, dppe), 40.18 (dd, $J_{PP} = 15$, 11; with ¹⁸³W satellites, $J_{WP} = 220$, dppe), 16.47 (ddd, $J_{PP} = 15$, 42, 69; with ¹⁸³W satellites, $J_{WP} = 293$, dppm) and -25.92 (d, $J_{PP} = 42$ Hz, dppm); ¹H NMR (CD₂Cl₂, 20 °C) δ 2.41 (m, 4 H, C₂H₄), 3.02 (br, 2 H, CH₂) and 6.90-7.70 (m, 40 H, C₆H₅).

Complex **9f** (Found: C, 61.65; H, 4.45. C₅₄H₄₆O₃P₄W requires C, 61.73; H, 4.41%): mass spectrum (FAB) m/z 1050 (M^+) and 1050 - 28n (n = 1-3); IR $(1,2-C_2H_4Cl_2, cm^{-1}) v(CO)$ 1938s and 1844s; ${}^{31}P-\{{}^{1}H\}$ NMR (CD₂Cl₂, 20 °C) δ 36.99 (d, J_{PP} = 22; with ¹⁸³W satellites, J_{WP} = 225, dppe), 6.89 (dt, J_{PP} = 30, 22; with ¹⁸³W satellites, $J_{WP} = 215$, dppm) and -25.61 (d, $J_{PP} = 30$ Hz, dppm); ¹H NMR (CD₂Cl₂, 20 °C) δ 2.55 (m, 4 H, C₂H₄), 2.79 (br, 2 H, CH_2) and 6.70–7.70 (m, 40 H, C_6H_5).

Reaction of complex 1 and PPh₃

Complex fac-[W(CO)₃(η^2 -dppf)(NCMe)] 1 (50 mg, 0.058 mmol) was treated with PPh₃ (16 mg, 0.06 mmol) for 20 h by the same method as described above. Three products were isolated: yellow $mer-[W(CO)_3(\eta^2-dppf)(PPh_3)]$ **12f** (2 mg, 3%), yellow $[W(CO)_4(\eta^2\text{-dppf})]$ (14 mg, 28%) and yellow fac- $[W(CO)_3$ - $(\eta^2$ -dppf)(PPh₃)] **12m** (16 mg, 26%).

Complex **12m** (Found: C, 60.67, H, 4.45. $C_{55}H_{43}FeO_3P_3W$ requires C, 60.91; H, 4.00%): IR (1,2- $C_2H_4Cl_2$, cm⁻¹) ν (CO) 1965w, 1856s and 1840 (sh); $^{31}P-^{1}H$ NMR (CD₂Cl₂, 20 °C) δ 15.16 (dd, $J_{PP}=23$, 11; with ^{183}W satellites, $J_{WP}=224$), 20.72 (dd, $J_{PP}=23$, 66; with ^{183}W satellites, $J_{WP}=286$) and 28.66 (dd, $J_{PP}=66$, 11; with ^{183}W satellites, $J_{WP}=282$ Hz); ^{1}H NMR (CD₂Cl₂, 20 °C) δ 3.98–4.40 (m, 8 H, C_5H_4) and 6.80–7.60 (m, 35 H, C_6H_5).

Complex **12f** (Found: C, 60.99; H, 3.92. $C_{55}H_{43}FeO_3P_3W$ requires C, 60.91; H, 4.00%): mass spectrum (FAB) m/z 1084 (M^+), 822 (M^+ – PPh₃) and 822 – 28n (n = 1–3); IR (1,2- $C_2H_4Cl_2$, cm⁻¹) v(CO) 1940s, 1846s and 1828 (sh); ³¹P-{¹H} NMR (CD₂Cl₂, 20 °C) δ 16.26 (d, J_{PP} = 28; with ¹⁸³W satellites, J_{WP} = 224) and 19.05 (t, J_{PP} = 28; with ¹⁸³W satellites, J_{WP} = 210 Hz); ¹H NMR (CD₂Cl₂, 20 °C) δ 3.90 (s, 2 H), 4.26 (s, 2 H), 4.53 (s, 2 H), 4.80 (s, 2 H, C_5H_4) and 6.80–7.60 (m, 35 H, C_6H_5).

Reaction of complex 1 and PPh₂Me

Complex 1 (50 mg, 0.058 mmol) was treated with PPh₂Me (12 mg, 0.06 mmol) for 20 h by the method described above. Three products were isolated: yellow [W(CO)₄(η^2 -dppf)] (2 mg, 4%), yellow *mer*-[W(CO)₃(η^2 -dppf)(PPh₂Me)] **13m** (4 mg, 7%) and yellow *fac*-[W(CO)₃(η^2 -dppf)(PPh₂Me)] **13f** (52 mg, 88%).

Complex **13m** (Found: C, 58.50; H, 4.23. $C_{50}H_{41}FeO_{3}P_{3}W$ requires C, 58.75; H, 4.01%): mass spectrum (FAB) m/z 1022 (M^{+}), 994 (M^{+} – CO), 822 (M^{+} – PPh₂Me) and 822 – 28n (n = 1–3); IR (1,2-C₂H₄Cl₂, cm⁻¹) ν (CO) 1960w, 1852s and 1842 (sh); ³¹P-{¹H} NMR (CD₂Cl₂, 20 °C) δ 1.50 (dd, J_{PP} = 13, 65; with ¹⁸³W satellites, J_{WP} = 272), 17.62 (dd, J_{PP} = 13, 23; with ¹⁸³W satellites, J_{WP} = 224) and 21.35 (dd, J_{PP} = 23, 65; with ¹⁸³W satellites, J_{WP} = 292 Hz); ¹H NMR (CD₂Cl₂, 20 °C) δ 1.65 (d, 3 H, J_{PH} = 7, Me), 4.16 (s, 2 H), 4.25 (br, 4 H), 4.28 (s, 2 H, $C_{5}H_{4}$) and 7.00–7.70 (m, 30 H, $C_{6}H_{5}$).

Complex **13f** (Found: C, 58.52; H, 4.13. $C_{50}H_{41}FeO_3P_3W$ requires C, 58.75; H, 4.01%): mass spectrum (FAB) m/z 1022 (M^+), 994 (M^+ – CO), 822 (M^+ – PPh₂Me) and 822 – 28n (n = 1–3); IR (1,2-C₂H₄Cl₂, cm⁻¹) v(CO) 1938s, 1846s and 1830 (sh); ³¹P-{¹H} NMR (CD₂Cl₂, 20 °C) δ – 3.71 (t, J_{PP} = 27; with ¹⁸³W satellites, J_{WP} = 228) and 19.83 (d, J_{PP} = 27; with ¹⁸³W satellites, J_{WP} = 216 Hz); ¹H NMR (CD₂Cl₂, 20 °C) δ 1.90 (d, 3 H, J_{PH} = 5 Hz, Me), 3.99 (s, 2 H), 4.28 (s, 2 H), 4.50 (s, 2 H), 4.73 (s, 2 H, C_5H_4) and 7.00–7.60 (m, 30 H, C_6H_5).

Isomerizations

Complexes 4f and 7f. Typically, an NMR tube was charged with fac-[W(CO)₃(η^2 -dppf)(η^1 -dppm)] 4f (15 mg) and CD₂Cl₂ (2 cm³) under nitrogen. The isomerization was carried out at room temperature and monitored by ³¹P NMR spectroscopy. It was complete after 72 h, showing only the resonances for 5m. Isomerization of complex 7f to give 7m takes 1 week to complete at room temperature, but only 3 h are required at 80 °C.

Complexes 4m and 6m. A typical reaction: a Schlenk flask (50 cm³) was charged with mer-[W(CO) $_3$ (η^2 -dppf)(η^1 -dppm)] 4m (40 mg) and 1,2-dichloroethane (10 cm³). The flask was placed in an oil-bath at 80 °C and the reaction was monitored by IR spectroscopy in the CO stretching region. The spectra showed no further change after 6 h. The solvent was evaporated under vacuum and the residue separated by TLC, affording 5m in 90% yield. Isomerization of complex 6m was carried out at 80 °C, producing 7m in 71% yield. No reaction was observed at ambient temperature.

Complex 4f in the presence of acid. The complex (18 mg, 0.015 mmol) and dichloromethane (10 cm³) were placed in a Schlenk flask (50 cm³) containing a magnetic stirring bar and a rubber septum. An ether solution of HBF₄ (20 μ l, excess) was added *via* a syringe. The mixture was stirred at ambient temperature for 2 h, and evacuated under vacuum. The residue was subjected to TLC, eluting with CH₂Cl₂-*n*-hexane (1:1, v/v).

The material from the yellow band gave mer-[W(CO)₃(η^2 -dppf)(η^1 -dppm)] **4m** (14 mg, 78%) (Found: C, 61.42; H, 4.22. $C_{62}H_{50}$ FeO₃P₄W requires C, 61.71; H, 4.18%): mass spectrum (FAB) mlz 1205 (M^+), 1205 – 28n (n = 1–3) and 821 (M^+ – dppm); IR (1,2- C_2H_4 Cl₂, cm⁻¹) v(CO) 1961w and 1853s; ³¹P-{¹H} NMR (CD₂Cl₂, 20 °C) δ 21.66 (dd, $J_{\rm PP}$ = 23, 66; with ¹⁸³W satellites, $J_{\rm WP}$ = 288, dppf), 16.83 (dd, $J_{\rm PP}$ = 23, 33; with ¹⁸³W satellites, $J_{\rm WP}$ = 230, dppf), 14.66 (ddd, $J_{\rm PP}$ = 33, 38, 66; with ¹⁸³W satellites, $J_{\rm WP}$ = 275, dppm) and –25.06 (d, $J_{\rm PP}$ = 38 Hz, dppm); ¹H NMR (CD₂Cl₂, 20 °C) δ 3.23 (br, 2 H, CH₂), 4.12 (br, 4 H, C_5H_4), 4.21 (br, 4 H, C_5H_4) and 6.80–7.70 (m, 40 H, C_6H_5).

Complex 6f in the presence of acid. Isomerization of fac-[W(CO)₃(η²-dppf)(η¹-dppe)] 6f (20 mg, 0.016 mmol) in the presence of an excess amount of HBF₄ was carried out and worked up in a fashion identical to that above. Yellow mer-[W(CO)₃(η²-dppf)(η¹-dppe)] 6m (12 mg, 60%) was obtained as the major product. Mass spectrum (FAB): m/z 1221 (M^+), 823 (M^+ – dppe) and 823 – 28n (n = 1–3); IR (1,2-C₂H₄Cl₂, cm⁻¹) v(CO) 1960w and 1854s; ³¹P-{¹H} NMR (CD₂Cl₂, 20 °C) δ 21.53 (dd, $J_{\rm PP}$ = 23, 66; with ¹⁸³W satellites, $J_{\rm WP}$ = 291, dppf), 18.27 (ddd, $J_{\rm PP}$ = 33, 34, 66; with ¹⁸³W satellites, $J_{\rm WP}$ = 273, dppe), 16.26 (dd, $J_{\rm PP}$ = 23, 34; with ¹⁸³W satellites, $J_{\rm WP}$ = 225, dppf) and –13.45 (d, $J_{\rm PP}$ = 34 Hz, dppe); ¹H NMR (CD₂Cl₂, 20 °C) δ 1.62 (m, 2 H), 2.36 (m, 2 H, C₂H₄), 4.12 (s, 2 H), 4.18 (s, 2 H), 4.22 (s, 2 H), 4.24 (s, 2 H, C₅H₄) and 6.60–7.80 (m, 40 H, C₆H₅).

Reactions of complex 4f

With dppe. The complex (23 mg, 0.019 mmol) and dppe (75 mg, 0.19 mmol) were placed in a Schlenk flask (50 cm³) containing a magnetic stirring bar. The flask was fitted with a rubber septum, evacuated, and backfilled with nitrogen. After introducing dichloromethane (15 cm³), the solution was stirred at ambient temperature for 48 h. The mixture was then dried under vacuum and the residue separated by TLC, eluting with CH_2Cl_2 -n-hexane (1:1, v/v). Three products were isolated in order of appearance on the TLC plate: yellow mer-[W(CO)₃- $(\eta^2$ -dppm)(η^1 -dppf)] 5m (11 mg, 48%), yellow fac-[W(CO)₃- $(\eta^2$ -dppf)(η^1 -dppe)] 6f (60 mg, 25%) and yellow fac-[W(CO)₃(η^2 -dppf)(η^1 -dppm)] 4f (50 mg, 21%).

With PMe₃. A Schlenk flask (50 cm³) was charged with *fac*-[W(CO)₃(η^2 -dppf)(η^1 -dppm)] **4f** (10 mg, 0.008 mmol) and 1,2-dichloroethane (10 cm³) under nitrogen. A toluene solution of PMe₃ (12 µl, 0.012 mmol) was introduced by a microsyringe. The mixture was stirred at ambient temperature for 30 h. The solvents were removed under vacuum and the residue separated by TLC, eluting with *n*-hexane–dichloromethane (1:1, v/v). The known complex *fac*-[W(CO)₃(η^2 -dppf)(PMe₃)]¹² **10f** (6 mg, 83%) and **5m** (1 mg, 10%) were obtained.

With CO. A two-necked flask (100 cm³) was equipped with a magnetic stir bar. One neck was connected to an oil bubbler and the other had an inlet tube for introduction of carbon monoxide gas into the solution. A solution of fac-[W(CO)₃(η^2 -dppf)(η^1 -dppm)] 4f (20 mg, 0.017 mmol) in 1,2-dichloroethane (10 cm³) was transferred to the flask and saturated with CO gas. The mixture was stirred at ambient temperature for 48 h with slow bubbling of CO through the solution. The mixture was dried under vacuum and the residue separated by TLC. The known complex [W(CO)₄(η^2 -dppf)]¹⁴ 11 (10 mg, 70%) and 5 (3 mg, 15%) were obtained.

Results and Discussion

Preparation of compound 3

The syntheses of fac-[W(CO)₃(η^2 -dppf)(NCMe)] ¹² 1 and fac-

[W(CO)₃(η^2 -dppm)(NCMe)] ⁹ **2** have been previously described. The analogous complex fac-[W(CO)₃(η^2 -dppe)(NCMe)] **3** is prepared in a similar fashion by treating [W(CO)₃(NCMe)₃] with equimolar dppe at room temperature. The IR spectrum of **3** in the carbonyl region resembles those recorded for **1** and **2**, indicating similar structures. The ³¹P NMR spectrum of **3** displays one resonance at δ 46.25, which is significantly downfield from those recorded for **1** (δ 22.4) and **2** (δ -11.06).

Preparation and isomerization of complexes 4f and 5f

The complex fac-[W(CO)₃(η^2 -dppf)(η^1 -dppm)] **4f** is initially afforded from the reaction of fac-[W(CO)₃(η^2 -dppf)(NCMe)] **1** and dppm at ambient temperature. Isomerization of **4f** readily takes place at 25 °C to give mer-[W(CO)₃(η^2 -dppm)(η^1 -dppf)] **5m** together with a switch of the chelate ligand from dppf to dppm. Complete transformation from **4f** to **5m** takes 72 h at 25 °C, but only 4 h are required at 50 °C. In the presence of acid, however, mer-[W(CO)₃(η^2 -dppf)(η^1 -dppm)] **4m** is obtained as the sole product. Compound **4m** is indefinitely stable at room temperature, but it slowly converts into **5m** in hot 1,2-dichloroethane solution (80 °C). The other isomer fac-[W(CO)₃(η^2 -dppm)(η^1 -dppf)] **5f** is not isolable but only detected by ³¹P NMR spectroscopy as an intermediate during the reaction of fac-[W(CO)₃(η^2 -dppm)(NCMe)] **2** and dppf, leading to **5m**. The results are summarized in Scheme 1.

It is obvious that complexes **4f** and **5f** are the kinetic products of the reactions, while **5m** is most stable thermodynamically. However, when dppe, PMe₃ or CO is present, **5m** is obtained together with fac-[W(CO)₃(η^2 -dppf)(η^1 -dppe)] **6f**, fac-[W(CO)₃(η^2 -dppf)(PMe₃)] **10f** and [W(CO)₄(η^2 -dppf)] **11**, respectively (Scheme 2). This indicates that substitution of the η^1 -diphosphine ligand is a competitive reaction. Nevertheless, once the meridional isomer is formed, it is quite resistant to ligand dissociation, such that **5m** does not react with PMe₃ at 50 °C.

The different reactivity between complexes 4f and 5f can be rationalized in terms of the structures of parent compounds 1 and 2. Since the dppf ligand of 1 can modify its steric bite by twisting the cyclopentadienyl rings, the phenyl groups and the NCMe ligand are staggered. However, the four-membered dppm ring of 2 constrains the phenyl groups to being eclipsed to the axial NCMe and CO ligands. So compound 5f would

sustain stronger steric repulsions between phosphine ligands than **4f** and is more susceptible to isomerization.

Scheme 3

Preparation and isomerization of complexes 6f and 7f

Reactions of fac-[W(CO)₃(η^2 -dppf)(NCMe)] 1 with dppe and its subsequent isomerization processes are summarized in

Scheme 3. The results closely resemble the reactions with dppm shown above, except that a dimetallic complex fac, fac- $[\{W(CO)_3(\eta^2\text{-dppf})\}_2(\eta^1:\eta^1\text{-dppe})]$ **6ff** is produced and both **6f** and **7f** are isolable. Standing a solution of pure **6f** at 25 °C yields **7m** and **6ff**, but under acidic conditions **6m** is obtained solely without forming the dimetallic species. It is apparent that eliminating a dppe ligand from **6f** is essential to give **6ff**, while **6m** is resistant to ligand dissociation. Furthermore, no isomerization of **6ff** is evidenced. This is contrary to the reaction of fac- $[Mo(CO)_3(NCMe)\{\eta^2\text{-Ph}_2PN(Pr^i)PPh(dmpz)\}]$ and dppe to produce mer,mer- $[\{Mo(CO)_3[\eta^2\text{-Ph}_2PN(Pr^i)PPh(dmpz)]\}_2$ - $(\eta^1:\eta^1\text{-dppe})]$. ¹¹

On the other hand, treating fac-[W(CO)₃(η^2 -dppe)(NCMe)] **3** with dppf at room temperature produces [W(CO)₄(η^2 -dppe)] (33%), fac-[W(CO)₃(η^2 -dppe)(η^1 -dppf)] **7f** (29%) and mer-[W(CO)₃(η^2 -dppe)(η^1 -dppf)] **7m** (26%). It is likely compound **7f** is afforded initially, following by isomerization to give **7m** as well as disproportionation to yield the W(CO)₄ complex.

Preparation and isomerization of complex 8f

The acetonitrile ligand of fac-[W(CO)₃(η^2 -dppm)(NCMe)] **2** is readily replaced by dppe, but leading to fac-[W(CO)₃(η²dppe)(η^1 -dppm)] 9f and mer-[W(CO)₃(η^2 -dppe)(η^1 -dppm)] 9m (Scheme 4). Phosphorus-31 NMR spectroscopy has been applied to assess the progress of reaction. The spectrum of reaction mixture after 2 h shows the presence of fac- $[W(CO)_3(\eta^2\text{-dppm})(\eta^1\text{-dppe})]$ 8f along with small quantities of mer-[W(CO)₃(η^2 -dppm)(η^1 -dppe)] **8m** and **9f**. The quantities of 8f, 8m and 9f are about equal in 24 h. After 3 d, 9f and 8m are present as the major products together with a minor amount of 8f and 9m. Although this transformation is slow, attempts to isolate all the components by TLC only afford 9f and 9m. It is probable that the conversion of 8 into 9 is accelerated by acid contaminant on the silica gel. Schenk and Hilpert 10 previously reported an analogous reaction of fac-[Mo(CO)₃(η²-dppm)-(NCMe)] and dppe to yield fac-[Mo(CO)₃(η^2 -dppe)(η^1 -dppm)], where the four-membered chelate ring of dppm is opened up to leave an η¹-co-ordinated dppm while a more stable five-membered chelate ring is formed by dppe. The ultimate formation of 9m indicates the operation of ring strains in determining the products.

Reaction of complex 1 and bulky monophosphine

Treatment of fac-[W(CO)₃(η^2 -dppf)(NCMe)] **1** with PPh₃ and PPh₂Me affords fac-[W(CO)₃(η^2 -dppf)(PPh₃)] **12f** and fac-[W(CO)₃(η^2 -dppf)(PPh₂Me)] **13f**, respectively, which then rearrange to give mer-[W(CO)₃(η^2 -dppf)(PPh₃)] **12m** and mer-[W(CO)₃(η^2 -dppf)(PPh₂Me)] **13m**. The analogous complexes fac-[W(CO)₃(η^2 -dppf)(L)] (L = PMe₃, PPh₂H, or PPh₂OH) are stable under similar conditions. ¹² Obviously, the energy barrier for $fac \longrightarrow mer$ transformation is reduced as the steric bulk of the ligands increases.

Characterization of new compounds

Compounds **5f**, **8m** and **8f** cannot be isolated in a pure form and were characterized only by ^{31}P NMR spectroscopy. The remaining complexes form crystalline solids and give satisfactory analyses (C, H). Their FAB mass spectra display the molecular ion and ions corresponding to successive loss of three carbonyls. The IR spectra in the carbonyl region for the facial isomers show three strong bands, presumably due to a disrupted C_3 symmetry for the W(CO)₃ group, while the meridional geometry is indicated by one weak and two medium to strong absorption bands. $^{2-6,9,15}$

Identification of these new complexes is unambiguously substantiated by ³¹P NMR spectroscopy. Their spectra are assigned on the basis of chemical shifts and coupling patterns.^{2-4,10,16} In general, the facial isomers have a plane of symmetry and would

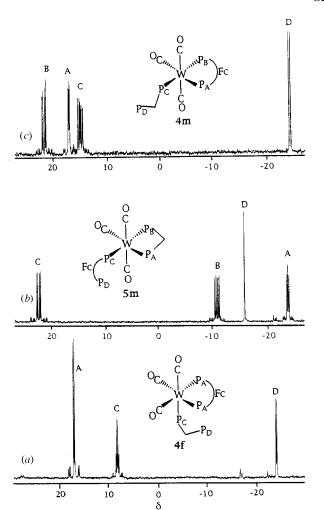

Fig. 1 The $^{31}P-\{^{1}H\}$ NMR spectra of (a) $fac-[W(CO)_{3}(\eta^{2}-dppf)(\eta^{1}-dppm)]$ **4f**, (b) $mer-[W(CO)_{3}(\eta^{2}-dppm)(\eta^{1}-dppf)]$ **5m** and (c) $mer-[W(CO)_{3}(\eta^{2}-dppf)(\eta^{1}-dppm)]$ **4m** in $CD_{2}Cl_{2}$ solution

display two ³¹P resonances for the co-ordinated phosphines and one resonance for the pendant phosphine group, while the meridional isomers present four resonance signals. Typical spectra of **4f**, **4m** and **5m** are illustrated in Fig. 1 for com-

parison. For **4f** a doublet signal at δ 16.91 and a doublet of doublets at δ 8.17 accompanied by ¹⁸³W satellites are assigned to the co-ordinated dppf and dppm moieties, respectively, and an upfield doublet resonance at δ –24.16 without ¹⁸³W satellites is assigned to the pendant dppm group. On the other hand, **4m** and **5m** display three complex resonances for the co-ordinated phosphines due to coupling between the inequivalent phosphorus atoms and to the ¹⁸³W atom.

The co-ordination shifts, $\Delta = \delta_{monodentate} - \delta_{free}$ ligand, and chelation shifts, $\Delta_{R} = \delta_{chelate} - \delta_{monodentate}$, of the diphosphine ligands are of interest in these complexes. The co-ordination shifts for dppm, dppe and dppf are comparable, averaging +32, +24 and +28 ppm, respectively. In contrast, the chelation shifts are more diverse, where the four-membered dppm rings are shielded (-30 ppm), the five-membered dppm rings are deshielded (+25 ppm) and the dppf rings are only slightly affected (+5 ppm). Although the theoretical aspects of the ring contribution remain elusive, Garrou ¹⁷ has proposed the general utility of Δ and Δ_{R} for structural assignments of transition-metal phosphine complexes.

Possible isomerization mechanism

The facial–meridional isomerism may be reasonably accounted for by the reaction sequence shown in Scheme 5. Apparently, three bulky phosphines in a facial arrangement cause considerable steric repulsions, leading to ready dissociation of the η^1 -disphosphine ligand to give **I**, or opening up the η^2 -disphosphine ring to give **II**. The resulting square-pyramidal intermediates could then undergo site exchange, presumably through a trigonal-bipyramidal transient with one of the diphosphine ligands at the axial position and ring closing to yield the final products. 18,19 Alternatively, an associative mechanism to generate a seven-co-ordinate, 20-electron intermediate $[W(CO)_3(\eta^2\text{-diphos})(\eta^2\text{-diphos}')]$ seems improbable based on the steric considerations.

Since isomerization of complex **4f** produces **5m** solely without forming **4m**, the site-exchange rate for **II** should be much faster than that for **I**. One possible explanation is the ring constraints of **I** increasing the energy separation between the more stable square-pyramidal and less stable trigonal-bipyramidal structures. Furthermore, adding PMe₃ to a solution of **4f** does not give $[W(CO)_3(\eta^1\text{-dppm})(\eta^1\text{-dppf})(PMe_3)]$ or $[W(CO)_3(\eta^2\text{-dppm})(PMe_3)]$. This means that, once the intermediate **II** is

Scheme 5

Scheme 7

4f ⇒ 4m 6f ⇒ 6m

formed, the subsequent site exchange and ring-closing processes must be very rapid.

This mechanism is further supported by a kinetic study. The rate constants measured for the reaction of complex **4f** with CO and PMe₃ at 25 °C are comparable, being 2.17×10^{-5} and 2.13×10^{-5} s⁻¹, respectively. Furthermore, both reactions are observed to be first order in metal substrate and zero order in

PMe₃ or CO concentration at a pressure close to 1 atm (*ca.* 101 325 Pa). This clearly indicates that the rate-determining step is fission of the W-dppm bond.

Rearrangement of complex **4m** to **5m**, **6m** to **7m** and **8m** to **9m** probably occurs *via* the pathway shown in Scheme 6. It is apparent the ability of diphosphine ligands to form a chelate ring is dppe > dppm > dppf. The five-membered dppe ring is obviously preferable to the strained, four-membered dppm ring. On the other hand, though the chelated dppf ligand presents little ring strain, its large bite angle $(ca. 98^\circ)^{12}$ combined with the steric bulk of the phenyl groups could impose strong steric interactions with the adjacent ligands. This makes dppf less favorable as a chelate ligand than dppm.

Vila and Shaw 20 previously reported a trace of acid-induced rapid interconversion between the facial and meridional isomers of [W(CO)₃(η^2 -dppm)(PEt₃)] and a hydrido intermediate, [WH(CO)₃(η^2 -dppm)(PEt₃)]⁺, was evidenced. 20 It is likely that protonation of complex **4f** or **6f** generates a fluxional seven-coordinate species, which then undergoes fast intramolecular rearrangement by placing the η^1 -diphosphine ligand *trans* to the η^2 -disphosphine group to reduce steric crowding. Subsequent deprotonation of this species could afford the meridional isomer (Scheme 7). A pseudo-three-fold rotation is likely involved to account for this facile rearrangement. It has been shown that the energy barrier for a ligand three-fold rotation decreases dramatically as the co-ordination number of the metal changes from six to seven. 21
