

58. Glycosylidene Carbenes

Part 3

Synthesis of Spirocyclopropanes¹⁾

by **Andrea Vasella*** and **Christian A. A. Waldruff**

Organisch-chemisches Institut, Universität Zürich, Winterthurerstrasse 190, CH-8057 Zürich

(22.II.91)

Thermolysis of the glycosylidene-derived *O*-benzylated diazirine **1** in the presence of *N*-phenylmaleimide (**2**), acrylonitrile (**3**), dimethyl fumarate (**4**), or dimethyl maleate (**5**) led in good yields to mixtures of the spirocyclopropanes **6/7**, **8–11**, **12/13**, and **12/13/16/17**. The diastereoselectivity depends upon the alkene. The cycloaddition of **1** to **5** is not diastereospecific, in keeping with previous results. Deprotection of **12**, **13**, **16**, and **17** yielded the tetrols **14**, **15**, **18**, and **19**, respectively.

1. Introduction. – Glycosylidene-derived diazirines (1-aziglycoses) such as **1** [1] are precursors of glycosylidene carbenes [2] which form glycosides by insertion into O–H bonds of phenols and alcohols [3] [4]. Glycosylidene carbenes are expected to be ambiphilic/nucleophilic [5] and to form spirocyclopropanes by cycloaddition to acceptor substituted alkenes [6]. *Descotes* and coworkers have indeed shown that photolysis of *O*-acylated 1,1-diazides in the presence of acrylonitrile leads to a mixture of diastereoisomeric spirocyclopropanes [7]. The scope of this method appears to be restricted to *O*-acylated diazides and to alkenes which are resistant to the conditions of photolysis. The restriction to acylated diazides is presumably due to a stepwise formation of carbenes *via* azidonitrenes, which lead to side reactions with *O*-benzylated diazides [8]. We have examined the reaction of the benzyl-protected aziglucose **1** with *N*-phenylmaleimide (**2**), acrylonitrile (**3**), dimethyl fumarate (**4**), and dimethyl maleate (**5**)²⁾.

Results and Discussion. – 2.1. *Addition of 1 to N-Phenylmaleimide (2; see Scheme 1).* Treatment of the diazirine **1** with excess *N*-phenylmaleimide (**2**) in 1,4-dioxane at room temperature for 12 h yielded the two cyclopropanes **6** and **7** (80%) in a ratio of 9:1. The diastereoselectivity leading to the preferred formation of **6** is probably due to an unfavourable steric interaction in the transition state of the rate-determining step between the C(1) and C(5) substituents and the BnO group at C(3').

Both **6** and **7** are pyrrolidine-2,5-diones, as evidenced by the typical C=O absorption at 1775 and 1710 cm⁻¹ in their IR spectra and by the C=O s's between 171.33 and 170.11 ppm in the ¹³C-NMR spectra. In the IR spectra, the

¹⁾ Presented at the 'XVIII International Carbohydrate Symposium', Yokohama, Japan, 12th–17th August 1990, Abstr. PL-05.

²⁾ Pyranoses with a spirocyclopropane unit at C(2) [9], C(4) [10], or C(5) [11] have been prepared before, also known is a furanose with a spirocyclopropane unit at C(4) [11]. Monosaccharides with annulated cyclopropyl groups are also known [11–15].

characteristic cyclopropane C–H bands are detected at 3030 cm^{-1} . The ^1H -NMR spectra show the cyclopropane protons as *d*'s between 2.69 and 3.04 ppm with $^3J(1,5)$ of 5.8 and 6.7 Hz, in agreement with known values for similar compounds [16]. In the ^{13}C -NMR spectra, the cyclopropane C-atoms resonate between 32.68 and 29.36 ppm and the spiro C-atoms at 73.79 (**6**) and 73.67 ppm (**7**). The configuration of the minor product **7** was assigned on the basis of a NOE of H–C(6') on irradiation at H–C(5). The assignment is supported by a comparison of $\delta(\text{H–C}(3'))$ and $\delta(\text{H–C}(4'))$ of **6** and **7** (4.02 and 3.84 ppm for **6**; 4.17 and 4.01 ppm for **7**) showing the deshielding effect on H–C(3') and H–C(4') of **7** by the *cis*-oriented imide function. The conformation of the tetrahydropyran ring is not significantly affected by the spiro-annellation.

2.2. Addition of 1 to Acrylonitrile (3; see Scheme 2). The diazine **1** reacted in excess **3** (room temperature, 12 h) to give a mixture of the four isomeric cyclopropanes **8**, **9**, **10**, and **11** (70%, 9:5.5:2:1). In the two major products (58%), the CN group is located below the average plane of the tetrahydropyran ring and, in the major product **8**, away from BnO–C(8). In the minor product **10** and **11**, the CN group is located above the average plane of the tetrahydropyran ring and, in the more abundant **10**, in the neighbourhood of BnO–C(8).

The CN function in **8–11** gives rise to a typical band at 2250 cm^{-1} in the IR spectra and *s*'s in the ^{13}C -NMR spectra resonating between 118.96 and 117.94 ppm. The cyclopropane ring is evidenced by the IR band between 3030 and 3010 cm^{-1} . In the ^1H -NMR spectra, **8**, **10**, and **11** show three typical signals for the cyclopropane protons

between 1.88 and 1.13 ppm; the coupling constants are 10.6 or 9.9 Hz for $^3J_{cis}$, 7.2 or 6.4 Hz for $^3J_{trans}$, and 6.2–5.5 Hz for 2J . Similar values for coupling constants in a cyclopropane ring have been reported [17]. In the ^{13}C -NMR spectra, the cyclopropane C-atoms give rise to signals between 16.30 and 14.78 ppm for C(2) and between 8.12 and 4.65 ppm for C(1). The spiro C-atoms resonate between 65.28 and 63.11 ppm.

The configurations were mainly assigned on the basis of NOE experiments. Compound **8** shows NOE's between H–C(7) and H–C(1), and between H–C(8) and H_{pro-S}–C(2). Both H–C(1) and H_{pro-S}–C(2) show a $^3J_{cis}$ of 9.9 Hz and a NOE between each other. The deshielding effect of the CN group on H–C(5) (δ = 3.78 ppm, as compared to 3.51, 3.43, and 3.52 ppm for **9**, **10**, and **11**, respectively) supports this assignment. The cyclopropane **10** shows NOE's between H–C(5) and H_{pro-S}–C(2) and between H–C(7) and H_{pro-R}–C(2) evidencing that the CN group is attached to the cyclopropane C-atoms located above the average plane of the tetrahydropyran ring. The orientation of the CN group is deduced from $^3J_{cis}$ = 10.6 Hz, as observed in the signals of H–C(1) and H_{pro-S}–C(2), and from a NOE between these two protons. With **11**, one finds all three possible NOE's, i.e. between H–C(8) and H–C(1), H–C(7) and H_{pro-R}–C(2), and between H–C(5) and H_{pro-S}–C(2). In this isomer, one finds $^3J_{cis}$ for H–C(1) and H_{pro-R}–C(2) and also a NOE between these protons. For **9**, one finds a NOE between H–C(1) and H–C(5). The signal of H–C(7) is shifted to lower fields (δ = 3.98 ppm, as compared to 3.70, 3.75, and 3.67 ppm for **8**, **10**, and **11**, respectively).

2.3. Addition of **1 to Dimethyl Fumarate (**4**) and to Dimethyl Maleate (**5**; see Scheme 3).** Some cases of non-stereospecific cycloadditions of ambiphilic carbenes to electrophilic alkenes have been reported [18]. Glycosylidene carbenes are less reactive towards MeOH than methoxymethyl carbene [2], and this presumably on account of the BnO groups.

Scheme 3

a) 1,4-Dioxane, r.t., 12 h, 43% **12**, 29% **13**. b) 1.5 bar H₂, Pd(OH)₂/C, MeOH, r.t., 45 min, quant. c) 1,4-Dioxane, r.t., 12 h, 20% **16**, 17% **12**, 12% **13**, 11% **17**. d) With mixture of **12/13/16/17**, 4 h (2 bar), 10 h (1.2 bar) H₂, Pd(OH)₂/C, MeOH, r.t.; 98% **14/15/18/19**.

These electron-withdrawing substituents are expected to lower the nucleophilic properties of the carbene and to decrease the stability of the zwitterionic intermediate in a non-concerted cycloaddition (cf. [19] [20]) by interacting with the oxycarbenium center.

This could lead to a stereospecific addition to acceptor-substituted alkenes. We examined this question by exposing **1** to dimethyl fumarate (**4**) and to dimethyl maleate (**5**)³.

The reaction of **1** with excess **4** in 1,4-dioxane at room temperature for 12 h gave two crystalline cyclopropanes **12** and **13** (72%) in a ratio of 3:2 which were separated by HPLC⁴. The analogous reaction with **5**⁵ provided the four cyclopropanes **16/12/13/17** (60%; 1.8:1.5:1.1:1). HPLC gave pure **16** and a mixture of the other three compounds. The *cis*-configuration of the cyclopropane protons of **16** and **17** were assigned on the basis of large vicinal coupling constants (> 10 Hz).

To obtain the unprotected cyclopropanes, each of the benzyl ethers **12**, **13**, and **16** was hydrogenated in MeOH at room temperature for 45 min in the presence of Pd(OH)₂/C at 1.5 bar H₂ pressure to give, in quantitative yield, the tetrols **14**, **15**, and **18**, respectively (Scheme 3), which were purified by flash chromatography. To assign the configuration of **19** and hence of **17**, the mixture **12/13/16/17** obtained from the addition to dimethyl maleate (**5**) was hydrogenated under similar conditions to give the cyclopropanes **14/15/18/19**. The desired compound **19** was isolated by flash chromatography.

The presence of the COOMe groups in the cyclopropanes **12–19** is readily detected in the IR, ¹H-, and ¹³C-NMR spectra. The constitution of **12**, **13**, and **16**, the constitutional changes in the formation of **14**, **15**, **18**, and **19**, and particularly the presence of the cyclopropane ring are evident from the IR and NMR spectra. The cyclopropane protons of **12**, **13**, **14**, and **15** give rise to *d*'s between 3.26 and 2.55 ppm with ³*J*(1,2) = 7.7 Hz, in keeping with a *trans*-configuration. The compounds **16**, **18**, and **19** show *d*'s between 2.53 and 2.43 ppm with a ³*J*(1,2) of 10.4 to 11.6 Hz, typical for *cis*-configured cyclopropane protons⁶). This assignment is confirmed by NOE's between these protons (absent in the *trans*-configured cyclopropanes). The orientation of the COOMe groups was determined by NOE's between H–C(8) and H–C(1) and between H–C(5) and H–C(2) of **12** and **14**. The cyclopropanes **13** and **15** show a NOE between H–C(7) and H–C(2). The same NOE was observed for **16** and **18**. A NOE between H–C(8) and H–C(1) of **16** was also observed. For compound **19**, one sees a NOE between H–C(5) and H–C(2). The downfield shift of H–C(7) of **12** (δ = 4.21 ppm; for **13** and **16**, 3.36 and 3.73 ppm, respectively) and of **14** and **19** (δ = 3.60 ppm, as compared to 3.36 and 3.32 ppm of **15** and **18**, respectively) support the assignments, and so does the downfield shift of H–C(8) of **19** (δ = 4.05 ppm, in comparison with 3.82, 3.79, and 3.67 ppm of **15**, **16**, and **18**, respectively) and of H–C(5) of **16** (δ = 4.14 ppm, as compared to 3.80 and 3.57 ppm for **12** and **13**, respectively).

The MS of **14**, **15**, **18**, and **19** show a peak at *m/z* 275, corresponding to $[M + 1 - \text{MeOH}]^+$, but M^+ was only found in the MS of **15** and **18**. The greater ease with which **14** and **19** lose MeOH may be rationalized by a facile lactonization involving OH–C(8). This constitutes an additional, albeit weak evidence for the proposed configurations and hints at a way to differentiate the ester functions in **14** and **19**.

Thus, *O*-benzyl-protected glycosylidene-derived diazirines form spiro[cyclopropane-tetrahydropyrans] under very mild thermal conditions. While the addition to *N*-phenyl-maleimide (**2**) shows a satisfactory degree of diastereoselectivity, this is not so for the

³) Conceivably, the diazine **1** may undergo isomerization to a diazo compound [3]. A 1,3-dipolar cycloaddition [22] of this diazo compound to **4** and to **5** could form 4,5-dihydro-3*H*-pyrazoles [23], which might yield cyclopropanes by extrusion of N₂. Both cases are known, *i.e.* reactions, where 4,5-dihydro-3*H*-pyrazoles were isolated or observed [12b] [16a] [23] and reactions, where these intermediates evaded detection [25]. We found no evidence for the formation of diazo ethers or 4,5-dihydro-3*H*-pyrazoles in the reactions of **1** with **2**, **3**, **4**, or **5** (but *cf.* [4]).

⁴) Both photolysis (–15°, HPK125 Philips high-pressure Hg lamp with a Solidex filter) and thermal decomposition (room temperature) of **1** in the presence of **4** in CH₂Cl₂ yielded **12** and **13** in a ratio of 2.5:1, besides several by-products, in markedly lower yields as compared to the thermal reaction in 1,4-dioxane.

⁵) The dimethyl maleate (**5**) contained less than 1% of dimethyl fumarate (**4**; GLC: SE-25, 80°).

⁶) The cyclopropane protons of **17** (spectrum of a mixture **12/13/17** in CDCl₃) appear as two *d*'s at 2.47 and 2.34 ppm with ³*J*(1,2) = 11.1 Hz.

additions to the other alkenes we examined. It remains to be seen if this lack of selectivity is restricted to glycosylidene-derived diazirines with an equatorial substituent at C(2).

We thank the Swiss National Science Foundation and F. Hoffmann-La Roche AG, Basel, for generous support.

Experimental Part

General. See [2]. Solvents and liquid reagents were distilled, solid reagents were recrystallized; 1,4-dioxane was dried over Na and MeOH over Mg, both were kept under N₂. Powdered 4-Å molecular sieves (Union Carbide) were activated for 6 h at 280° and kept under N₂. Qual. TLC: detection by treating with a soln. of 5% (NH₄)₆Mo₇O₂₄·4H₂O and 0.1% Ce(SO₄)₂·4H₂O in 10% H₂SO₄ or with a soln. of 5% vanillin in conc. H₂SO₄.

Cyclopropanation of 1 with N-Phenylmaleimide (2). Under N₂, a soln. of 471 mg (2.7 mmol) of 2 in 1 ml of 1,4-dioxane was stirred in the presence of 0.1 g of 4-Å molecular sieves for 30 min at r.t. Then, 150 mg (0.27 mmol) of 1 were added quickly, the mixture was stirred at r.t. for 12 h, diluted with 5 ml of CH₂Cl₂, and filtered through Celite. The Celite was washed several times with CH₂Cl₂. The combined filtrates were evaporated. FC (hexane/AcOEt 9:1) of the residue gave 137 mg (72%) of 6 and 15 mg (8%) of 7.

Cyclopropanation of **1** with Dimethyl Fumarate (**4**). Under N₂, a soln. of 1 g (7 mmol) of **4** in 5 ml of 1,4-dioxane was stirred in the presence of 1.5 g of 4-Å molecular sieves for 30 min at r.t. Then, 400 mg (0.7 mmol) of **1** were added quickly, the mixture was stirred at r.t. for 12 h, diluted with 5 ml of CH₂Cl₂, and filtered through *Celite*. The *Celite* was washed several times with CH₂Cl₂. The combined filtrates were evaporated. FC (pentane/Et₂O 3:1) of the residue yielded 338 mg (72%) of **12/13** 3:2. In contact with MeOH, some **12** crystallized. The isomers were

separated completely by prep. HPLC (pentane/Et₂O 7:3, 16 ml/min). Crystallization of pure **13** from Et₂O/hexane at –25° afforded colourless needles; **12** was recrystallized in MeOH to give a white powder.

Dimethyl (1R,2R,5R,6R,7S,8R)-6,7,8-Tris(benzyloxy)-5-[(benzyloxy)methyl]-4-oxaspiro[2.5]octane-1,2-dicarboxylate (12): Prep. HPLC: *t_R* 13.4 min. *R_f* (pentane/Et₂O 1:1) 0.44. General Procedure for the Debenzylation. Hydrogenation at 1.5 bar H₂ pressure of a soln. of the benzyl ether in MeOH in the presence of Pd(OH)₂/C (20% Pd) at r.t. for 45 min, followed by filtration through *Celite* and evaporation of the solvent yielded the crude product, which was purified by FC (CH₂Cl₂/MeOH 7:1).

Dimethyl (1R,2R,5R,6R,7S,8R)-6,7,8-Trihydroxy-5-(hydroxymethyl)-4-oxaspiro[2.5]octane-1,2-dicarboxylate (14). Hydrogenation of 32 mg (0.048 mmol) of **12** in 2 ml of MeOH in the presence of 52 mg of Pd(OH)₂/C gave 15 mg (100%) of **14**. *R_f* (CH₂Cl₂/MeOH 4:1) 0.42. $[\alpha]_D^{25} = +13.1$ (*c* = 1, MeOH).
