Porcine pancreas lipase-catalyzed hydrolysis of symmetrical 2-(ethoxycarbonyl)propane-1,3-diyl dihexanoate, under the modified conditions of the *Seebach* protocol, afforded a desymmetrized monohexanoate in 40-51% yield with 91-94% ee, even in a gram-scale reaction. The absolute configuration of a half-hydrolyzed (–)-product was determined to be (*R*) by conversion to a known 2-methylpropane-1,3-diol derivative. Samarium iodide-induced radical cyclization of 2-oxo-3-phenylethylamine with a C₄ unit on the N-atom, derived from the racemic monohexanoate, afforded a 3-phenylpiperidine derivative as a model construction of the A–D ring system of lysergic acid.

1. Introduction. - Lysergic acid (1), a tetracyclic indole derivative with two stereogenic centers, is the core unit of ergot alkaloids showing a wide spectrum of biological activities [1] such as prolactin inhibition, anti-Parkinsonian effect, and depression of hypertension. The total synthesis of racemic 1 has been reported by nine research groups [2], and two groups have successfully achieved the asymmetric synthesis [3]. We have explored a novel aziridination from guanidinium ylides and aromatic (or unsaturated) aldehydes, applicable to asymmetric synthesis [4], and designed the synthesis of bioactive N-containing compounds, including lysergic acid (1), using the formed aziridine as a key synthetic intermediate. Our retrosynthetic strategy of 1 is shown in Scheme 1, in which aziridine 3, derived from guanidinium ylide 4 and 4-formyl-1*H*-indole, is reacted with an isobutyl-like C_4 unit 5 to build the D ring after construction of the A-B-C tricyclic ring system 2. Recently, we reported the cyclization from the 4-position of the 1H-indole skeleton to the 3-position by application of the Vilsmeier - Haack reaction [5]. In this paper, we present the practical preparation of an optically active C₄ unit as the partial component of the D ring by enzymatic desymmetrization of 2-(ethoxycarbonyl)propane-1,3-diyl dihexanoate and the model cyclization for the A-D ring system of lysergic acid (1) by using the corresponding racemic C₄ unit.

2. Results and Discussion. – 2.1. Enzymatic Desymmetrization of 2-(Ethoxycarbonyl)propane-1,3-diyl Dihexanoate (9). In 1990, Ehrler and Seebach reported the enzymatic desymmetrization of 2-(ethoxycarbonyl)propane-1,3-diyl dihexanoate (9) [6], in which a half-hydrolyzed (–)-monohexanoate (–)-10 was obtained in 48% yield with 84% ee, when porcine pancreas lipase (PPL) was used as an enzyme in the

presence of MeOH as co-solvent. Therefore, we decided to re-examine *Seebach*'s protocol [6] using PPL and, thus, prepared the starting dihexanoate 9 and racemic monohexanoate (\pm) -10, as an authentic half-hydrolyzed product, from diethyl malonate according to the combination of reported procedures [6]¹) as shown in *Scheme 2*.

Scheme 2. Preparation of 2-(Ethoxycarbonyl)propane-1,3-diyl Dihexanoate (9) and the Racemic Monohexanoate (\pm) -10

The results of the PPL-catalyzed desymmetrization are summarized in *Table 1*. At first, reactions with a small scale (0.1 g) of the dihexanoate **9** were examined as preliminary experiments (*Entries 1-7*). Application of the *Seebach*'s co-solvent system [6] of MeOH (*Entry 1*) as well as the use of THF as co-solvent (*Entry 7*) satisfactorily afforded an optically active half-hydrolyzed (–)-monohexanoate (–)-**10**, in spite of

long reaction time in the latter case. Next, gram-scale reactions were carried out under these two conditions. The product (-)-10 was obtained in increased chemical yield without loss of enantioselectivity in the THF system (*Entry 9*), whereas lower enantioselectivity was observed in the MeOH one (*Entry 8*). Unfortunately, trial of further scale-up operation in the THF system resulted not only in longer reaction time, but also in lower enantioselectivity. Thus, it was concluded that a few gram scale operation in the THF system could be the best condition of this PPL-catalyzed desymmetrization of 2-(ethoxycarbonyl)propane-1,3-diyl dihexanoate (**9**).

Ehrler and *Seebach* had addressed the optical purity of the (-)-monohexanoate (-)-10 by conversion to the corresponding *Mosher* ester [6]; however, we newly applied chiral HPLC method after benzoylation, in which a *CHIRALCEL OJ-H* column (hexane/PrOH 100:1) was used. The absolute configuration of the (-)-monohexanoate (-)-10 has never been determined. Therefore, we determined it by chemical correlation with the known (+)-(*R*)-2-methyl-1,3-propanediol derivative (+)-(*R*)-16 [8] as shown in *Scheme 3*. The (-)-monohexanoate (-)-10 was reduced with diisobutylaluminum hydride (DIBAH) after protection of the OH moiety with the (*t*-Bu)Ph₂Si (TBDPS) group (\rightarrow (+)-11). The obtained (+)-alcohol (+)-12 was subjected to the successive treatments of protection with the (benzyloxy)methyl (BOM) group (\rightarrow (+)-13), reduction with DIBAH (\rightarrow (-)-14), introduction of a *p*-toluenesulfonyl (Ts) group (\rightarrow (-)-2-methylpropanediol derivative (-)-16. Thus, the opposite sign of optical rotation against the known (+)-compound with (*R*)-configuration indicated

that the absolute configuration of (-)-monohexanoate (-)-10, obtained by PPLcatalyzed desymmetrization of dihexanote 9, should be (R).

2.2. Model Construction of the A-D Ring System of Lysergic Acid (1). Next, we planed to prepare 5-(ethoxycarbonyl)-1-methyl-3-phenylpiperidine core 21 by reaction of the C₄ unit 17, derivable from (±)-2-(ethoxycarbonyl)propane-1,3-diyl monohexanoate (±)-10, and N-methyl-2-oxo-2-phenylethylamine (18) for the model construction of 21, *i.e.*, the A-D ring system of lysergic acid (1) as outlined in Scheme 4.

The starting amino ketone **18** was prepared as a trifluoroacetate salt from 2hydroxy-*N*-methyl-2-phenylethylamine (**22**) by *Swern* oxidation after protection of the amino group with (*tert*-butoxy)carbonyl (Boc) group, followed by treatment with trifluoroacetic acid (TFA). On the other hand, according to route *A* in *Scheme 4*, conversion of the (\pm)-monohexanoate (\pm)-**10** to phosphonium salt **27** through bromination was attempted, but only elimination of the hexanoic acid moiety from the bromo derivative **25** occurred to give an olefinic phosphonium salt **26**. Alternatively, introduction of a different leaving group to (\pm)-**10** based on route *B* was achieved by mesylation; however, trials for *N*-alkylation of the amino ketone **18** or amino alcohol **22** using the mesylate **28** were failed; instead, mainly demesylation of **28** occurred (*Scheme 5*). These facts led us to alter the use of a C₄ unit from the monohexanoate **17** to the propane-1,3-diol derivative **31** lacking ester function (*Scheme 6*). Scheme 4. Synthetic Plan of 5-(Ethoxycarbonyl)-1-methyl-3-phenylpiperidine Core 21 for the Model Construction of the A – D Ring System of Lysergic Acid (1)

Preparation of some propane-1,3-diol derivatives without an ester function is depicted in *Scheme* 7. The key monosilyl derivative of 2-(ethoxycarbonyl)propane-1,3-diol **33** was prepared from (\pm) -**10** by silylation, followed by reductive hydrolysis. The monosilyl derivative **33** was also prepared by silylation of '2-(ethoxycarbonyl)propane-1,3-diol' (=ethyl 3-hydroxy-2-(hydroxymethyl)propanoate; **8**) under controlled conditions, in which the double-silylated product **34** was co-produced but could be re-used through desilylation. After protection of the OH group in **33** with the BOM or tetrahydropyranyl (THP) group, reduction with LiBH₄ afforded the corresponding diprotected 2-(hydroxymethyl)propane-1,3-diols **37** or **38**. Chemical modifications of them to bromides **39** and **40**, or methanesulfonates **41** and **42**, respectively, were achieved by either displacement of the OH group with Br or by mesylation.

Trials for conversion of bromides **39** and **40** to the corresponding phosphonium salts for *Wittig* reaction resulted in the recovery of the starting materials. On the other hand, although trials for *N*-alkylation with methanesulfonates **41** or **42** by using the amino ketone **18** as a nucleophile failed, desired alkylation products **43** or **44** were obtained as an inseparable mixture of diastereoisomers in 61 and 73% yields, respectively, when amino alcohol **22** was treated with Et₃N and KI in DMF (*Scheme 8*). However, it was found that oxidation products such as **45**, produced by *Swern* oxidation, were quite labile in pure forms. Survey of the literature indicated no reports on the oxidation of amino alcohols like **43** or **44**, whereas smooth conversion of a 1-alkyl- [9] or an *N*-acylsubstituted amino alcohol, **46** and **48** [10], respectively, to the corresponding ketone products **47** and **49**, respectively, were observed. Therefore, the amines **43** or **44** for oxidation were changed to the corresponding *N*-Boc-protected derivatives.

Oxidation of *N*-Boc-amino alcohol **51**, derived from 2-hydroxy-2-phenylethylamine (**50**), with pyridinium dichromate (PDC) in DMF, as expected, gave the ketone **52** in

Scheme 6. Alternation of a C_4 Unit from the Monohexanoate **17** to Propane-1,3-diol Derivative **31** without an Ester Function

94% yield (*Scheme 9*). However, treatment of these *N*-Boc-protected amines **51** or **52** with BOM-protected methanesulfonate **41** did not afford alkylation products **53** or **54**. Fortunately, it was found that the original amino alcohol **50** itself could serve as a

Scheme 7. Preparation of Differently Diprotected Propane-1,3-diol Derivatives 39-42

nucleophile to give the desired alkylation product **55** although in moderate yield. The alcohol **55** was oxidized to *N*-Boc-amino ketone **54** by three kinds of methods with PDC in DMF (67%), by *Swern* oxidation (71%), and with MnO₂ in CH₂Cl₂ (83%), after protection of the amino function with Boc group. 2-Oxo-2-phenylethylamines **57** or **58** carrying an isobutyl-like C₄ unit as a precursor for the cyclization were prepared by deprotection of the (*t*-Bu)Me₂Si (TBS) group of **54**, followed by displacement of the OH group with a halogen atom (*Scheme 9*). The synthetic products **53** – **58** were formed as an inseparable mixture of diastereoisomers.

For C-C bond-formation of the halides **57** or **58** under *Wittig* reaction conditions, trials of conversion to the corresponding phosphonium salts were unsuccessful. Thus, we turned our attention to radical cyclization. Although almost no reaction occurred in the use of triethylborane-oxygen condition, application of samarium iodide (SmI₂)-induced cyclization to the iodide **58** in the presence of hexamethylphosphoric triamide (HMPA) afforded the desired 3-phenylpiperidine **59** as a separable *ca.* 1:1 mixture of diastereoisomers, albeit in 23% yield (see, *Entry 1* in *Table 2*). Thus, we examined this *Barbier*-type reaction under various conditions (*Table 2*), and slightly increased formation of the cyclized product **59** (32%) was observed, when an excess of samarium (Sm) [11] was used in the presence of HMPA under dilute concentration of the iodide **58** in THF (*Entry 5*). A cleaved product **60** was a major side-product in these reactions.

3. Conclusions. – In summary, we established the practical PPL-catalyzed desymmetrization of 2-(ethoxycarbonyl)propane-1,3-diyl dihexanoate, in which the best result in a few gram scale was obtained by the use of THF as co-solvent, and the absolute configuration of the desymmetrized (–)-monohexanoate was determined to be (R) by chemical conversion. Furthermore, SmI₂-induced radical cyclization of 2-oxo-3-phenylethylamine with an isobutyl-like C₄ unit on the N-atom, derived from the racemic monohexanoate, afforded 3-phenylpiperidine derivative as a model construction of A–D ring system of lysergic acid.

2) By Swern Oxidation. To a soln. of oxalyl chloride (0.01 ml, 0.12 mmol) in CH_2Cl_2 (0.1 ml) was added a soln. of DMSO (0.01 ml, 0.17 mmol) in CH_2Cl_2 (0.1 ml), followed by a soln. of **53** (45 mg, 0.08 mmol) in CH_2Cl_2 (0.4 ml) at -78° under Ar, and then the mixture was stirred at the same temp. for 1 h. After addition of a soln. of Et_3N (0.06 ml, 0.40 mmol) in CH_2Cl_2 (0.1 ml) at the same temp., the mixture was stirred for 1.5 h, the reaction was quenched with H_2O (2 ml), and then the mixture was extracted with CH_2Cl_2 (3 × 10 ml). The org. soln. was washed with brine (8 ml), dried, and evaporated. Purification of the residue by CC (acidic, hexane/AcOEt 10:1) afforded **54** (32 mg, 71%).

3) With MnO_2 . A mixture of **53** (503 mg, 0.90 mmol) and MnO_2 (3.12 g) in CH₂Cl₂ (5 ml) was stirred at r.t. for 2 d under Ar. After further addition of MnO_2 (0.52 g), the resulting mixture was stirred under the same conditions for 10 h. After removal of the MnO_2 through *Celite*[®] pad, the filtrate was evaporated. Purification of the residue by CC (acidic, hexane/AcOEt 15:1) afforded **54** (417 mg, 83%).

tert-*Butyl* N-(3-{[(Benzyloxy)methoxy]methyl]-2-(hydroxymethyl)propyl)-N-(2-oxo-2-phenylethyl)carbamate (**56**). To a soln. of **54** (362 mg, 0.65 mmol) in THF (3.5 ml) was added 1 mol soln. of TBAF in THF (0.78 ml, 0.78 mmol), and the mixture was stirred at r.t. for 4.5 h under Ar, and the reaction was quenched with sat. aq. NH₄Cl (2 ml), followed by H₂O (15 ml), and the mixture was extracted with AcOEt (3×20 ml). The org. soln. was washed with brine (20 ml), dried, and evaporated. Purification of the residue by CC (acidic, hexane/AcOEt 2 :1) afforded **56** (266 mg, 93%). Colorless oil. tert-*Butyl* N-(2-[[(Benzyloxy)methoxy]methyl]-3-iodopropyl)-N-(2-oxo-2-phenylethyl)carbamate (**58**). A mixture of 1*H*-imidazole (152 mg, 2.24 mmol) and PPh₃ (294 mg, 1.12 mmol), and I₂ (285 mg, 1.12 mmol) in CH₂Cl₂ (1 ml) was vigorously stirred at r.t. under Ar. To the resulting yellow suspension

was added a soln. of **56** (248 mg, 0.56 mmol) in CH₂Cl₂ (1.3 ml), and the mixture was stirred at r.t. for 4 h. After removal of insoluble materials by filtration, the filtrate was evaporated. Purification of the residue by CC (acidic, hexane/AcOEt 10 : 1) afforded **58** (242 mg, 78%). Pale yellow oil. IR (ATR): 1701 (CO). ¹H-NMR (400 MHz): 1.34, 1.50 (2*s*, 3 Me); 1.97 (*sept.*, J = 5.6, 0.5 H, CH); 2.06 (*sept.*, J = 5.6, 0.5 H, CH); 3.28 – 3.45 (*m*, CH₂); 3.53 (*dd*, J = 9.9, 6.6, 1 H, CH₂); 3.57 (*dd*, J = 9.8, 6.3, 1 H, CH₂); 3.65 (*dd*, J = 9.5, 4.4, 1 H, CH₂); 3.69 (*dd*, J = 9.9, 4.6, 1 H, CH₂); 4.61 (*s*, CH₂); 4.70 (*d*, J = 7.1, CH₂); 4.76 (*s*, CH₂); 7.22 – 7.30 (*m*, arom. tert-*Butyl* (5-{[(Benzyloxy)methoxy]methyl]-3-hydroxy-3-phenylpiperidin-1-yl)carbamate (**59**; Entry 5 in Table 2). A soln. of CH₂I₂ (0.03 ml, 0.31 mmol) in THF (0.1 ml) was added to a suspension of Sm metal (128 mg, 0.85 mmol) in THF (2 ml) at r.t. under sonication in Ar atomsphere. After addition of further THF (20 ml), the mixture was vigorously stirred for 1 h under sonication and for additional 0.5 h without sonication, and cooled to 0°. After addition of HMPA (0.28 ml, 1.61 mmol), the mixture was stirred under the same conditions for 20 min, to which a soln. of **58** (48 mg, 0.09 mmol) in THF (1 ml) was slowly added, and the mixture was stirred at 0° for 1 h. After quenching with sat. aq. Roschelle salt (6 ml), insoluble materials were filtered through Celite® pad, and the filtrate obtained was extracted with AcOEt (3 × 10 ml). The org. soln. was washed with H₂O (10 × 3 ml) and brine (10 ml), and dried and evaporated. Purification of the residue by CC (acidic, hexane/AcOEt 8:1), followed by prep. TLC (hexane/acetone 5:1, triple developments), afforded **59** as a mixture of the (3*R**,5*R**)- (5 mg, 13%; a colorless oil) and the (3*S**,5*R**)-diastereoisomers (7 mg, 19%; a colorless oil).
