DOI: 10.1039/b610614e

The reductive amination of aldehydes or ketones using Ph<sub>2</sub>SiH<sub>2</sub> or PhSiH<sub>3</sub> has been effectively promoted by the direct use of Bu<sub>2</sub>SnClH–pyridine *N*-oxide as a catalyst; this method has advantages in terms of its mild conditions and wide application to various carbonyls and amines, including aliphatic examples.

The reductive amination of aldehydes and ketones is one of the most useful routes to secondary amines, in which the three components of carbonyl, amine and reductant are easily combined in one pot. The advantage of this reaction is that there is no need to isolate intermediate imines, in particular, in cases where combinations of aromatic amines and aliphatic carbonyls would give expectedly unstable imines. The choice of reductant is very critical because the undesirable reduction of starting carbonyls must be suppressed. A number of reducing agents have been developed, sodium cyanoborohydride (NaBH<sub>3</sub>CN),<sup>2</sup> sodium triacetoxyborohydride (NaBH(OAc)<sub>3</sub>)<sup>3</sup> and borane-pyridine (BH<sub>3</sub>-Py)<sup>4</sup> being the most commonly used. However, these reagents have serious problems, requiring excess amounts of starting amines and acidic conditions. We have already overcome these problems by developing the Bu<sub>2</sub>SnClH system, which effects the reductive amination with equimolar amounts of amines under mild and neutral conditions.<sup>5,6</sup> However, the use of aliphatic amines caused the decomposition of the tin hydride. In addition, an equimolar amount of environmentally hazardous tin reagent is necessary, and so a catalytic application is desirable. Apodaca and Xiao demonstrated reductive amination with phenylsilane (PhSiH<sub>3</sub>) in the presence of a catalytic amount of Bu<sub>2</sub>SnCl<sub>2</sub>. More recently, Kangasmetsa and Johnson have improved the same system by using microwave-assisted heating.8 They suggest that Bu<sub>2</sub>SnClH, generated in situ, is an active species. However, discussions on the effects of Bu<sub>2</sub>SnCl<sub>2</sub> and by-product water are unclear. Since Bu<sub>2</sub>SnClH has been already noted to be an elegant reagent for reductive amination and easily available by redistribution between Bu<sub>2</sub>SnCl<sub>2</sub> and Bu<sub>2</sub>SnH<sub>2</sub>, without forming any acidic by-products, we have re-investigated the reaction by the direct use of Bu<sub>2</sub>SnClH as the catalyst. Consequently, we found that the addition of a small amount of pyridine N-oxide achieved a catalyst

system that is applicable to a wide range of carbonyls and amines, including aliphatic examples, under mild conditions (Scheme 1).

Initially, we examined hydride sources and additives in reductive aminations using a catalytic amount of Bu<sub>2</sub>SnClH, as shown in Table 1. Triethylsilane (Et<sub>3</sub>SiH) did not give the desired amine 3a in satisfactory yield (Table 1, entry 1). In contrast, diphenylsilane (Ph<sub>2</sub>SiH<sub>2</sub>) completed the reaction within 15 min to afford 3a in 89% yield (Table 1, entry 2). The yields of 3a and 3b were increased to quantitative by the addition of only 2 mol% of HMPA (Table 1, entries 3 and 4). A similar effect to HMPA has been observed in the equimolar reaction.<sup>5</sup> However, because the use of hazardous HMPA should be avoided, we investigated the affect of other additives, such as DMPU, DMF and phosphine oxides. While these additives did not give satisfactory results, pyridine N-oxide worked well, giving amine 3b in 94% yield when combined with PhSiH<sub>3</sub> instead of Ph<sub>2</sub>SiH<sub>2</sub> (Table 1, entry 6). Moreover, an interesting effect was observed in the reaction with acetophenone (1b). Although the system of Bu<sub>2</sub>SnClH–HMPA and PhSiH<sub>3</sub> only promoted the reaction of **1b** with 58% yield (Table 1, entry 8), the addition of pyridine N-oxide gave a higher yield of 89% (Table 1, entry 9).

Next, we applied the optimized system, using 2 mol% of Bu<sub>2</sub>SnClH-pyridine N-oxide, to the reaction between aliphatic ketones or aldehydes with amines (Table 2). In all entries, substoichiometric quantities of PhSiH<sub>3</sub> performed the reactions, in contrast to the microwave-assisted method that required two equivalents of the silane to consume all the imine formed.<sup>8</sup> This result may indicate a different mechanism to the reduction. The reductive amination of aliphatic ketones or aliphatic aldehydes with aromatic amines readily took place to give high yields (Table 2, entries 1–7). In particular, the reaction of the primary aliphatic aldehyde 1g with 2a (Table 2, entry 7) demonstrates the advantage of this catalyst system over the equimolar one because only 30% yield of 3i was given, even with the stoichiometric use of Bu<sub>2</sub>SnClH-HMPA. A stronger base, aliphatic amine 2c, could be also applied without decomposition of the tin hydride and PhSiH<sub>3</sub> (Table 2, entry 8), while facile decomposition of tin hydrides by the amine has been reported.<sup>5</sup> Even combinations of aliphatic ketone and aliphatic amines were allowed, giving 3k and 3l (Table 2, entries 8 and 9).

Apodaca's system<sup>7</sup> was not applied to aliphatic aldehydes or aliphatic primary amines, perhaps because of the decomposition of PhSiH<sub>3</sub> by amine and water, and microwave-assisted method<sup>8</sup> is not applicable to ketones. In contrast, Table 2 shows that various

substrates, including aliphatic ketones, aldehydes and amines, could be employed without decomposition of the tin hydride and PhSiH<sub>3</sub>. Unfortunately, combinations of aliphatic aldehydes and aliphatic amines did not provide the desired amines. This is the limitation of our method at this stage.

As shown in Scheme 2, it is noteworthy that the reduction of an isolated imine hardly took place, while the direct reductive amination of the 1a with 2a was smoothly promoted. The presence of water, generated by the formation of the imine, is likely to be crucial in this regard.<sup>9</sup>

A plausible catalytic cycle is shown in Scheme 3. Initially, a pentacoordinated tin hydride, Bu<sub>2</sub>SnClH-L (A), is generated by simple mixing of  $Bu_2SnClH$  and L (L = pyridine N-oxide), which has a reactive Sn-Cl bond in an apical position of the trigonal bipyramidal structure.<sup>5</sup> Next, the formation of iminium salt **B** allows successive intramolecular hydride attack to furnish the tin amide C. The fact that no reduction of the isolated imine to amine 3 takes place under anhydrous conditions strongly suggests that the silyl hydride hardly reacts with the Sn-N bond of C.10 Hence, the tin amide C is protonated by H<sub>2</sub>O, generated during the imine formation step, furnishing the desired amine 3 and generating tin hydroxide **D**. In the final step, **D** reacts with PhSiH<sub>3</sub> to regenerate the tin catalyst A. Rapid completion of the catalytic cycle would suppress decomposition of the tin hydride, even in the presence of basic aliphatic amines. Thus, the catalyst tin hydride immediately reacts with imine prior to interaction with the starting amine. In addition, the low concentration of hydride A seems to disturb the interaction.

Scheme 2

Scheme 3 A plausible catalytic cycle.

In summary, silyl hydrides such as Ph<sub>2</sub>SiH<sub>2</sub> and PhSiH<sub>3</sub> promoted reductive amination under very mild conditions in the presence of a catalytic amount of Bu<sub>2</sub>SnCIH complex. These reducing systems were superior to conventional reducing agents in terms of their wide applicability to substrates.
