Polyoxamic acid **4a** is prepared by a short and efficient process in which the key steps are the highly diastereoselective nucleophilic epoxidation of the D-threitol-derived alkene **6** using potassium *tert*-butylperoxide, followed by reaction of the oxirane **7a** with ammonia.

We have shown recently that diastereoisomerically pure  $\gamma$ -hydroxy threonine derivatives **3** can be prepared by reaction of the stereoisomeric 2-nitro-2-(*p*-tolylthio)oxiranes **2** with ammonia in a stereospecific process which occurs with inversion of configuration.<sup>1</sup> The oxiranes were prepared by nucleophilic epoxidation of the 1-nitro-1-(*p*-tolylthio)alkene **1** derived from p-isopropylideneglyceraldehyde; use of potassium *tert*-butylperoxide gave predominantly the *anti* stereoisomer, whilst use of lithium *tert*-butylperoxide gave predominantly the syn stereoisomer, both with moderate selectivity. We now report an application of this method to a concise and flexible approach to polyoxamic acid **4a**,<sup>2,3</sup> which is also applicable in principle to the C-2 epimer **4b**.

The alkene **6** was prepared by condensation of (p-tolylthio)nitromethane<sup>4</sup> with the aldehyde **5**,<sup>5</sup> itself prepared in two steps from commercially available 2,3-isopropylidene-Lthreitol (Scheme 1). Nucleophilic epoxidation of the alkene **6** with potassium *tert*-butylperoxide gave a mixture of the two stereoisomeric oxiranes **7a** and **7b**, (87%). Analytical HPLC indicated a d.e. of 92% in favour of the major isomer, to which we have assigned *anti*-stereochemistry **7a** on the basis of our previous experience,<sup>1</sup> and also on the basis of subsequent transformations. Epoxidation of the alkene **6** with lithium *tert*-butylperoxide gave the oxiranes **7a** and **7b** (86%), with a d.e. of 66% in favour of **7b**. On the basis of our previous results,<sup>1</sup> the oxirane **7a** was an ideal precursor to (+)polyoxamic acid.

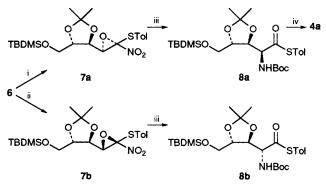

Reaction of the *anti*-oxirane **7a** with ammonia, followed by treatment with *tert*-butylpyrocarbonate, gave the *syn* Boc-

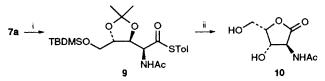

Scheme 1 Reagents and conditions: i, TolSCH<sub>2</sub>NO<sub>2</sub>, KOBu<sup>t</sup>, Bu<sup>t</sup>OH/ THF, 0 °C, then room temp. 3 h; ii, MeSO<sub>2</sub>Cl (3 equiv.),  $Pr^{i}_{2}NEt$  (3 equiv.), -78 °C, 2 h, 61% overall yield

protected  $\alpha$ -amino thioester **8a** (65%), after chromatographic separation of a trace of the *anti* thioester **8b**. Analogous treatment of the *syn*-oxirane **7b** gave the *anti*-Boc-protected  $\alpha$ -amino thioester **8b** (55%). Each of these compounds appeared to be stereoisomerically pure by <sup>1</sup>H NMR analysis. Under these reaction conditions there was no evidence of epimerisation of either  $\alpha$ -amino thioester. Subsequent treatment of the  $\alpha$ -amino thioester **8a** with aqueous trifluoroacetic acid gave polyoxamic acid **4a** (95%) (Scheme 2), whose spectroscopic properties were identical with those previously reported.<sup>5</sup>

For further confirmation of the structure, the oxirane 7a was converted to the corresponding N-acetyl y-lactone 10 (Scheme 3). Lactone 10 has frequently been prepared as a stable derivative of polyoxamic acid itself.<sup>5,6,7,8</sup> Reaction of the oxirane with ammonia as before, followed by treatment with acetic anhydride, gave the corresponding N-acetyl amino thioester 9 (84%), which could not be separated from trace amounts of the corresponding anti isomer. However, treatment of this mixture with trifluoroacetic acid in methanol resulted in conversion to the  $\gamma$ -lactone 10 (64%), which was isolated by chromatography and recrystallisation and found to be identical by comparison of <sup>1</sup>H NMR and <sup>13</sup>C NMR with spectra of authentic material supplied by earlier workers.<sup>5,6</sup> In addition, the mp and optical rotation of our sample compared favourably with the literature values.<sup>†</sup> We have prepared a 100 mg sample of lactone 10 using this method, and the procedure is certainly amenable to the preparation of gram quantities.

Scheme 2 Reagents and conditions: i, KOOBu<sup>t</sup>, THF, -78 °C, 2 h; ii, LiOOBu<sup>t</sup>, THF, -78 °C, 2 h; iii, NH<sub>3</sub> (0.880 aq., 5 equiv.), CH<sub>2</sub>Cl<sub>2</sub>, room temp., 2h, followed by Boc<sub>2</sub>O (10 equiv.), room temp. 2 h; iv, CF<sub>3</sub>CO<sub>2</sub>H/H<sub>2</sub>O (9:1), room temp. 1 h

Scheme 3 Reagents and conditions: i,  $NH_3$  (0.880 aq., 5 equiv.),  $CH_2Cl_2$ , room temp., 2h, followed by  $Ac_2O$  (10 equiv.),  $CH_2Cl_2$ , room temp., 2 h; ii,  $CF_3CO_2H/MeOH$  (1:1), room temp., 24 h

## J. CHEM. SOC., CHEM. COMMUN., 1994

We thank the SERC for a CASE award (N. J. P.), Professor E. J. Thomas and Dr G. J. Whitham for copies of spectra and detailed procedures for the preparation of 4, Professor M. S. Manhas for copies of spectra, and Pfizer Central Research for support.

Received, 17th August 1993; Com. 3/04997C

#### Footnote

<sup>†</sup> Our sample of lactone **10** had mp 141–142 °C and  $[\alpha]_{20}^{20}$  –105.5 (*c* 3.25, MeOH); literature values are 141–142 °C and  $[\alpha]_{20}^{20}$  –99.7 (*c* 2, MeOH)<sup>7</sup>. Provide a statistic statistic statistic statistics are statistical statistics. MeOH).<sup>7</sup> Previous reports had indicated a slightly higher mp:  $150-152 \text{ }^{\circ}\text{C}^2$  and  $147-150 \text{ }^{\circ}\text{C}.^8$
