A series of *N*-substituted 8-aminoxanthines (= 8-amino-3,7(or 3,9)-dihydro-1*H*-purine-2,6-diones) **8–16** and **34–37** were synthesized from the corresponding 8-nitroxanthines **1–7**, **30–33**, and 8-(phenylazo)xanthines **17** and **18** by catalytic reduction. Another approach was derived from 6-amino-5-(cyanoamino)uracils (= *N*-(6-amino-1,2,3,4-tetrahydro-2,4-dioxypyrimidin-5-yl)cyanamides) **23**, **24**, and **27** by base-catalyzed cyclization yielding **25–28**. All 8-aminoxanthines **8–29** and **34–37** were acetylated to the corresponding 8-(acetylamino)xanthines **40–57**, and prolonged heating led to 8-(diacetylamino)xanthines **58** and **59**. Several 8-aminoxanthines **8–13** were diazotized forming 8-diazoxanthines **60–64**. Coupling reactions of isolated **62** and **64** and intermediary formed 8-diazoxanthines with 1,3-dimethylbarbituric acid (= 1,3-dimethylpyrimidine-2,4,6(1*H*,3*H*,5*H*)-trione; **66**) resulted in 5-[(xanthin-8-yl)diazenyl]-1,3-dimethylbarbituric acids = 3,7(or 3,9)-dihydro-8-[2-(1,2,3,4-tetrahydro-1,3-dimethyl-2,4-dioxypyrimidin-5-yl)diazenyl]-1*H*-purine-2,6-diones **67–80**. The newly synthesized xanthine derivatives were characterized by the determination of their pK_a values, the UV- and NMR spectra, as well as elemental analyses.

Introduction. – Ever since the structural elucidation of the purine-ring system by *Emil Fischer* in 1898 [2], this heterocycle [3] has attracted much attention due to its wide distribution in nature in form of alkaloids, intermediates or end products of metabolism, and nucleosides and nucleic acid components. Numerous purine derivatives have been synthesized by the *Traube* synthesis [4] starting from pyrimidine-5,6-diamines and fusing the imidazole moiety or by attachment of the pyrimidine ring onto properly substituted imidazole derivatives [5]. In continuation of our efforts in the purine field, we concentrated our interest, after the 8-nitroxanthines [6], now on the little investigated 8-amino-*N*-methylxanthine derivatives. A few derivatives of this type have been described in the literature [7–16], but no systematic investigations of their properties and reactivities has been reported.

Synthesis. – The most straightforward syntheses of 8-aminoxanthines is the catalytic reduction of the corresponding 8-nitroxanthines of type **1**²⁾ [6]. Thus, we obtained from **1** and its 1-methyl- (**2**), 3-methyl- (**3**), 3-benzyl- (**4**), 1,3-dimethyl- (**5**), 3-benzyl-1-methyl- (**6**), and 1,3,7-trimethyl derivative **7** with Pd/C catalyst and H₂ in a

shaking apparatus in good yields the 8-aminoxanthines **8–14** (Scheme 1). Amino-xanthine **8** was prepared earlier by $\text{Na}_2\text{S}_2\text{O}_4$ reduction of 8-[(2,4-dichlorophenyl)azo]-[10][12] and 8-[(4-chlorophenyl)azo]xanthine [15], and 8-aminotheophylline (**12**) was synthesized from 8-chlorotheophylline with ethanolic ammonia [11] or by treatment of

Scheme 1

8-(benzylamino)theophylline in concentrated H_2SO_4 solution at room temperature [16]. Aminoxanthine **14** was also obtained already in 1882 from 8-bromocaffeine in a sealed tube at 130° with saturated alcoholic ammonia [7]. The 8-amino-7-methylxanthine (**15**) [17] and 8-aminotheobromine (**16**) [18] resulted from catalytic reductions of the corresponding 8-(phenylazo) derivatives **17** and **18**, and 8-amino-1,7-dimethylxanthine (**19**) was obtained by three different routes: *i*) catalytic reduction of 8-azido-1,7-dimethylxanthine (**20**), *ii*) treatment of 8-bromo-1,7-dimethylxanthine (**21**) with methanolic ammonia in an autoclave at 160° , and *iii*) by reaction of 8-(benzylamino)-1,7-dimethylxanthine (**22**) with concentrated H_2SO_4 solution at 50° giving the best yield, *i.e.*, 82%. Another approach to 8-aminoxanthines was achieved by base-catalyzed cyclization of 6-amino-1-benzyl-5-[cyanomethylamino]uracil (= 6-amino-1-benzyl-5-[cyano(methyl)amino]pyrimidine-2,4-(1*H*,3*H*)-dione = *N*-(6-amino-1-benzyl-1,2,3,4-tetrahydro-2,4-dioxypyrimidin-5-yl)-*N*-methylcyanamide; **23**) and its 3-methyl derivative **24** on treatment with 1*N* NaOH at 80° to give 8-amino-3-benzyl-7-methyl- (**25**) and 8-amino-3-benzyl-1,7-dimethylxanthine (**26**). Aminoxanthine **26** could also be obtained by methylation of **25** in DMF/ K_2CO_3 with MeI. Analogously reacted 6-amino-1-benzyl-5-[cyano(propyl)amino]uracil (**27**) and its 3-methyl derivative to **28** and **29**. Since the 8-nitro-9-methylxanthines **30–33** are easily available by nitration [6], the corresponding 8-amino-9-methylxanthines **34–37** were prepared again by catalytic reductions. Furthermore, 5-amino-1-methyl- (**38**) and 5-amino-1,3-dimethyl-6-(methylamino)uracil (**39**) yielded on treatment with bromocyan at pH 4.5 and room temperature directly **36** and **37**. All synthesized 8-aminoxanthines were converted into the corresponding 8-(acetylamino) derivatives **40–57** by heating in Ac_2O for a time depending on the solubility of the starting material. Prolonged heating of 8-aminocaffeine (**14**) and 8-amino-1,9-dimethylxanthine (**35**) yielded the 8-(diacetylamino) derivatives **58** and **59**, of which **58** is described in [19][20] but has never been fully characterized.

Various 8-aminoxanthines have been applied to diazotization reactions which were tried for the first time by *Gomberg* in 1900 [21] starting with 8-aminocaffeine (**14**) but without success of isolation of the reaction product. More successful was *H. Fischer* [10] in 1909 with 8-aminoxanthine (**8**) and *Robins* [15] in 1960 with 8-aminotheophylline (**12**) isolating 8-diazoxanthine (**60**) and 8-diazotheophylline (**64**), respectively, as yellowish solids. Analogously reacted **8–13** at low temperature to the corresponding 8-diazoxanthines **60–65** in high yields (*Scheme 2*). According to the instability of the diazofunction on heating, recrystallization of the reaction products was not possible, but their characterization could be achieved by their UV and NMR spectra.

Coupling reactions of the 8-diazoxanthines **62** and **64** with 1,3-dimethylbarbituric acid (= 1,3-dimethylpyrimidine-2,4,6-(1*H*,3*H*,5*H*)-trione; **66**) led to the corresponding azo dyes **67** and **68** which exist most likely according to their NMR spectra in the (*E*)-form stabilized by an intramolecular H-bond but also other tautomeric forms cannot be excluded *a priori*. The 8-amino-7- and 8-amino-9-methylxanthines did not allow to isolate the corresponding diazonium salts indicating that the imidazole moiety is responsible for the stabilization of the zwitterion structures. To show that diazotizations of **14–16**, **19**, **25**, **26**, **28**, **29**, and **34–37** took place in solution, the corresponding diazonium salts were also coupled with 1,3-dimethylbarbituric acid (**66**) to give, in analogy to **67** and **68**, the azo dyes **69–80**. The 8-diazoxanthines are stable in acidic

Scheme 2

solution but, in alkaline media, decomposition to unidentified products was observed. Interestingly, diazotheophylline (**64**) reacted in MeOH within 2 days to give 8-methoxy-1,3-dimethylxanthine [22] as shown in the *Figure*.

The UV spectra of 8-diazoxanthine (**60**) and 8-diazotheophylline (**64**) measured at pH 11 by *Jones and Robins* [15] have to be revised (*cf. Table 3*) since the authors have not realized the base lability of diazoxanthines leading to degradation.

Structures and Physical Properties. – The structures of the newly synthesized xanthine derivatives were characterized by UV spectra based on the pK_a values (*Tables 1–4*), by NMR spectra, and C,H,N analyses. Aminoxanthine **8** shows in the normal pH range one basic pK_a value at 2.00 and two acidic pK_a values at 8.48 and 12.01 describing the equilibria between cation (+) and neutral form (0), neutral form and monoanion (–) as well as monoanion and dianion (– –). The cations of all 8-aminoxanthines show very similar UV spectra indicating that protonation takes place in 7- or 9-position of the imidazole ring. The basic properties differ to some extent depending on the position of the various substituents. The 9-methyl derivatives are stronger bases than the 3-methyl- and 3-benzyl analogs which hinder partially the

Figure. Kinetics of 8-diazotheophylline (**64**) in MeOH in the dark

adjacent protonation site (see, *e.g.*, **34** vs. **10** and **11**). The first deprotonation step takes place in the pyrimidine moiety at H–N(3) whereby a substituent at N(9) acidifies this H-atom again for steric reasons. The second ionization in 8-aminoxanthine (**8**) takes place at the NH of the imidazole ring as seen from the similarity of the second pK_a values of **9**–**11**. If the imidazole moiety is substituted, a second acidic pK_a value could not be determined in the normal pH range. The ionization sequence in the unsubstituted **8** can also be derived from the NMR spectra comparing the chemical shifts of the H–N sites with those of the various *N*-methyl derivatives.

^{a)} Values within brackets are those of shoulders.

Similar conclusions can be drawn from the pK_a values and UV spectra of the 8-(acetylamino)xanthines **40–57** (Table 2). These xanthine derivatives are expectedly weaker bases than their precursors due to the acetylation of the amino groups.

The 8-diazoxanthines show a similar pattern identifying **60** and **61** as stronger acids as **62** indicating that the most acidic position is located at H–N(3). Anion formation at this site is associated with a strong bathochromic shift of the long-wavelength absorption band, whereas H–N(1) deprotonation in **62** causes a little red shift.

From a comparison of the pK_a values and UV spectra of the 5-[(xanthin-8-yl)diazanyl]-1,3-dimethylbarbituric acids **67–80** can be concluded that protonation in the cations takes place again at the imidazole moiety due to the very similar shape of the cation spectra (Table 4). The neutral molecular species are also very similar and exist most likely in the intramolecularly H-bonded (*E*)-form which show a characteristic signal in the NMR spectra at low field, at $\delta(H)$ 14.00–14.20. The first acidic pK_a in all derivatives is due to deprotonation at the barbituric acid moiety leading to a monoanion with an elongated chromophore associated with a red-shift of the long-wavelength absorption band.
