### Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

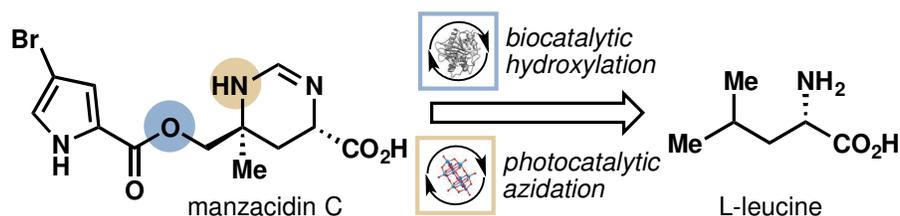

# Evolution of Biocatalytic and Chemocatalytic C–H Functionalization Strategy in the Synthesis of Manzacidin C

## Abstract

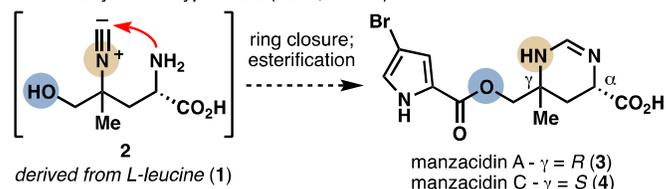

Due to their unique molecular architecture, the manzacidins have been the subject of intense synthetic efforts in the past two decades. Here, we describe two synthetic approaches towards manzacidin C that center on the enzymatic hydroxylation of unprotected L-leucine. This study also resulted in the discovery of novel synthetic methodologies, including a photocatalytic C–H azidation of unprotected amino acids. Additionally, we describe the use of hydroxylated L-leucine in the preparation of various densely-substituted pyrrolidines.

## Introduction

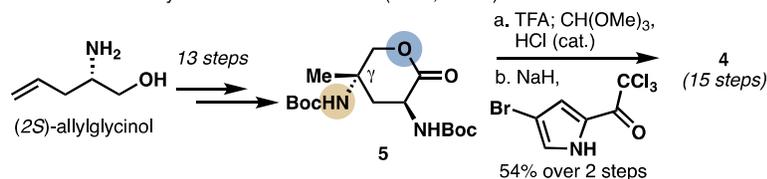

Commonly isolated from marine organisms, the bromopyrrole alkaloids<sup>1</sup> have long fascinated chemists due to their intricately complex structures. Three members of this family, manzacidins A–C were isolated by Kobayashi and co-workers in 1991 from the Okinawan sponge *Hymeniacidon* sp.<sup>2</sup> Although small, the manzacidins exhibit dense structural complexity (Figure 1A). Their core structure contains a 2,4-disubstituted bromopyrrole ester, as well as a

1  
2  
3 tetrahydropyrimidine motif featuring a carboxylic acid and two stereocenters, including a  
4 nitrogen-containing quaternary center.<sup>3</sup> In 2000, Ohfuné and co-workers established the first  
5 total syntheses of manzacidin A and C, sparking what has become a thriving area in the  
6 development of unique methodologies over the past eighteen years.<sup>4</sup> Their landmark strategy  
7 established lactone **5** as an advanced intermediate in thirteen steps, which can be converted to the  
8 natural product through a highly efficient 54% two-step protocol involving formation of the  
9 tetrahydropyrimidine motif, followed by bromopyrrole ester installation (Figure 1B). Since this  
10 seminal work, many approaches have developed or applied new methodology towards **5**,  
11 constituting a formal synthesis of manzacidin C (the  $\gamma$  epimer of **5** targeted for manzacidin A).<sup>5</sup>  
12 Although **5** appears structurally underwhelming, a literature survey suggests that approaches to  
13 this target remain non-trivial and typically require thirteen to fifteen steps. Alternative  
14 approaches that avoid the intermediacy of lactone **5** have also been developed, and in some  
15 cases, have resulted in some of the most step-efficient syntheses of the manzacidins.<sup>6</sup> Of note,  
16 Maruoka and co-workers quickly constructed manzacidin A with high stereocontrol via an  
17 enantioselective 1,3-dipolar cycloaddition, resulting in 17% overall yield in five steps.<sup>6a</sup>

9

10           Ohfuné's seminal publication briefly proposed that the manzacidins might have arisen  
11 from a hydroxylated isonitrile variant of L-Leu (**2**, Figure 1A). Isonitrile containing natural  
12 products are present in large abundance in marine sponges and tunicates.<sup>7</sup> In sponges, previous  
13 biosynthetic studies confirmed that inorganic cyanide is incorporated enzymatically to generate  
14 the isonitrile functionality, contrasting terrestrial isonitrile formation via  $\alpha$ -amino acids (AAs).<sup>7</sup>  
15 Isonitrile incorporation likely occurs through a transiently-formed carbocation starting from an  
16 alkene or tertiary alcohol. Biosynthetically, intermediate **2** may be constructed from L-Leu  
17 through a tandem C–H dihydroxylation sequence, followed by a Ritter-type reaction with  
18 inorganic cyanide at the  $\gamma$  carbon to install the isonitrile. In contrast to isonitrile functionality,  
19 hydroxyl group incorporation via biocatalytic C–H hydroxylation is well-documented. Of note,  
20 iron- and  $\alpha$ -ketoglutarate-dependent dioxygenases (Fe/ $\alpha$ KGs) are prolific in their ability to  
21 perform site- and stereospecific hydroxylation of AAs.<sup>8</sup> However, investigations into the  
22 synthetic potential of these hydroxylases have remained severely overlooked.<sup>9</sup> The ability to  
23 manipulate and repurpose Nature's repertoire of oxidation biocatalysts for synthetic  
24 transformations can result in a highly enabling approach towards constructing complex  
25 molecules.<sup>9</sup> To demonstrate this idea with the Fe/ $\alpha$ KGs, our laboratory chose to embark on a  
26 chemoenzymatic synthesis of manzacidin C, employing Ohfuné's proposal as inspiration. This  
27 full account traces the evolution of our chemoenzymatic approach towards this alkaloid and the  
28 subsequent application of enzymatic amino acid hydroxylation in the preparation of novel  
29 scaffolds.

## Results and Discussions

Towards the synthesis of manzacidin C, we envisioned a C–H functionalization strategy to access Ohfuné's hypothetical intermediate **2** (Figure 1C). Our strategy centered on efficient C–H amination/hydroxylation transformations from the cheap and abundant starting material, L-Leu (**1**). Although C–H functionalization strategies have become ubiquitous in complex molecule synthesis, examples demonstrating remote/distal C–H functionalization are rare; even more so for AAs (Figure S1).<sup>10</sup> Site specific C–H functionalization largely depends on the steric and electronic features present in a molecule.<sup>11</sup> Selective tertiary C–H bond functionalization is largely preceded, as electron deficient intermediates are stabilized via hyperconjugation, yielding a high level of site selectivity. Transition metal catalyzed C–H functionalization of AAs utilizing directing groups has recently been reported, but typically results in  $\beta$  functionalization due to preferential formation of a 5-membered metallacycle intermediate.<sup>12</sup> Hofmann-Löffler-Freytag (HLF) chemistry has previously been developed for  $\delta$  functionalization of AAs, but displays poor regio/stereocontrol and limited substrate scope.<sup>10c</sup> Known methods for C–H functionalization of AAs also require prudent protecting group strategies to mask highly reactive amine/carboxylic acid functional moieties.<sup>10,12</sup> Unlike traditional chemical methods, enzymatic C–H functionalization of AAs displays excellent regio/chemoselectivity and is able to operate on unprotected AAs.<sup>8</sup> Based on this information, our approach hinges on developing chemistry to selectively functionalize the  $\gamma$  and  $\delta$  positions of L-Leu, ideally without the addition of protecting groups.

We were initially drawn to the aforementioned Fe/ $\alpha$ KG family of enzymes due to their known activity in the hydroxylation of AAs en route to the biogenesis of nonribosomal peptides (NRPs).<sup>8,13</sup> Prior to our studies, C5 hydroxylation of L-leucine has previously been established

1  
2  
3 in the biosynthesis of the 4-methylproline motif of the nostopeptolides and the echinocandins,  
4 and the corresponding enzymes (LdoA and EcdK, respectively) have been biochemically  
5 characterized.<sup>14</sup> Due to previously reported limitations of LdoA and EcdK, we chose to  
6 characterize a putative leucine hydroxylase called GriE, which is implicated in the biosynthesis  
7 of griselimycin (Figure S2).<sup>15</sup> To this end, we first heterologously overexpressed GriE in *E. coli*  
8 as the C-His<sub>6</sub>-tagged protein, resulting in protein yield as high as 100mg/L. Combining GriE  
9 with L-Leu,  $\alpha$ -ketoglutarate, iron(II) sulfate, and L-ascorbic acid yielded 4-(OH)-L-Leu with  
10 complete conversion and high total turnover number (TTN = 7800). In tandem with our studies,  
11 Müller characterized GriE using a combination of *in vitro* studies and gene inactivation.<sup>16</sup>  
12 Further biochemical characterization showed that GriE displays a superior kinetic profile with its  
13 native substrate relative to previously reported Fe/ $\alpha$ KG enzymes.<sup>8b</sup> Encouraged by these  
14 observations, we conducted gram-scale hydroxylation of L-Leu with GriE, which following Boc  
15 protection and facile intramolecular cyclization, provided lactone **7** in 68% yield (Scheme 1A).

With an efficient protocol for producing gram quantities of **7** in hand, we next targeted an appropriate C–H amination transformation towards manzacidin C (Scheme 1B). Though intermolecular amination or azidation of tertiary C–H bonds is well represented in the literature,<sup>17</sup> established procedures to effect this transformation showed no reaction on **7**. This observation is attributed to a combination of steric hindrance (axial C–H bond) and electronic deactivation (proximal to ester oxygen).<sup>11a</sup> We next sought a more robust strategy to install the critical C–N bond. Intramolecular nitrene insertion has seen extensive use in natural product synthesis.<sup>18</sup> Of note, rhodium and silver mediated strategies have become particularly powerful approaches for effecting late-stage C–H amination. This disconnection has been applied in the syntheses of nitrogen-containing natural products such as the welwitindolinones, tetrodotoxin, pactamycin, and most notably manzacidin A and C by Du Bois.<sup>18,19</sup> Mechanistic studies indicate that a carbamate/sulfamate is first converted to an iminoiodinane (formally a nitrene) by the hypervalent iodine reagent (e.g., phenyliododiacetate (PIDA) or iodosobenzene (PhIO)). Subsequently, the metal catalyst (Ag(I) or Rh(II)) decomposes the iminoiodinane, yielding an

1  
2  
3 electrophilic metal nitrenoid, which performs insertion at proximal/electronically rich C–H  
4 bonds.<sup>18</sup> Our revised strategy involved installation of a carbamate moiety, which would  
5 participate in the proposed C–H amination (Scheme 1C). Towards carbamate **8**, we first  
6 converted lactone **7** to the Weinreb amide using a combination of trimethylaluminum and *N,O*-  
7 dimethylhydroxylamine hydrochloride, followed by carbamate formation with  
8 trichloroacetylisocyanate, resulting in 76% two-step yield on gram scale.<sup>19c</sup> At this stage, the  
9 critical C–H insertion could be tested. While catalytic rhodium(II) acetate dimer (Rh<sub>2</sub>(OAc)<sub>4</sub>)  
10 gave no reaction, the more active catalyst Rh<sub>2</sub>esp<sub>2</sub> yielded the desired product in 53% yield.<sup>20</sup>  
11 Previously reported conditions utilizing silver(I) triflate, bathophenanthroline, and PIDA in  
12 MeCN at 82 °C yielded oxazolidinone **9** in 65% (77% brsm).<sup>19a</sup> A two-step procedure involving  
13 Boc protection of the oxazolidinone, followed by methanolysis and lactonization yielded **5** in  
14 50% yield over two steps. This sequence constitutes a nine-step formal synthesis of manzacidin  
15 C (11% total yield), exhibiting complete stereocontrol through sequential C–H  
16 functionalizations.

Although our formal synthesis has improved step count relative to those previously reported, it lacks optimal synthetic ideality.<sup>21</sup> We identified that our critical C–N bond disconnection necessitated several functional group interconversions (FGIs) and protecting group manipulations (PGMs), leading to the poor ideality and step count. For this reason, a more efficient strategy to access **5** was sought. Concurrent to our effort in developing a chemoenzymatic synthesis of manzacidin C, we were also able to establish the substrate scope of the enzymatic hydroxylation.<sup>9a</sup> A key observation derived from the substrate profiling of GriE is that substitution at the  $\gamma$  position of the amino acid substrate is tolerated. In particular, 4-(OH)-Leu<sup>22</sup> could be oxidized to the corresponding dihydroxy amino acid (**11**) in moderate TTN (Scheme 2A). Elaboration of this compound to lactone **5** was next investigated. In particular, displacement of the tertiary alcohol with an appropriate nitrogenous nucleophile would closely mimic our postulated biosynthesis of the manzacidins. Inspired by the work of Shenvi and co-workers (Scheme 2B), as well as related work on Lewis/Brønsted Acid-mediated opening of butyrolactones, we reasoned prudent combination of Lewis Acid and nucleophile may yield our desired C–N bond.<sup>23</sup> This process likely proceeds through the intermediacy of a contact ion pair,

1  
2  
3 dictating stereochemical inversion during isonitrile formation. If stereoinvertive, this would  
4  
5 allow the synthesis of manzacidin A, which is epimeric at the  $\gamma$  position with respect to  
6  
7 manzacidin C (Figure 1A). Unfortunately, lactone **12** showed no reaction under Shenvi's  
8  
9 conditions. After screening various Lewis Acids in combination with azidotrimethyl silane  
10  
11 (TMSN<sub>3</sub>), we discovered combination of SnCl<sub>4</sub> in a 1:1 mixture of TMSN<sub>3</sub>:MeNO<sub>2</sub> resulted in  
12  
13 epimerization at the  $\gamma$  carbon (no other conditions showing any reaction). While disheartening,  
14  
15 this result suggested that a carbocation was transiently formed under the reaction conditions. If  
16  
17 this were the case, generating a more persistent/electron rich carbocation may yield the desired  
18  
19 reactivity. To test this hypothesis, lactone **13** was subjected to the reaction conditions (Scheme  
20  
21 2B, see Experimental Procedures for preparation of **13**), which resulted in the formation of the  
22  
23 desired azidocarboxylic acid **14**. Subsequent optimization of the reaction conditions improved  
24  
25 the yield of **14** to 82% yield (see Table S1). Attempting the azidolysis reaction in other solvents  
26  
27 besides MeNO<sub>2</sub> resulted in no reaction (see Table S1). Strict MeNO<sub>2</sub> requirement with SnCl<sub>4</sub> has  
28  
29 similarly been reported for intramolecular Freidel-Crafts reactions with cyclopropylesters,  
30  
31 wherein a carbocation intermediate was also proposed as a transient intermediate.<sup>24</sup> Similarly,  
32  
33 hydrobromic acid has been shown to open  $\alpha$ -tertiary lactones yielding a tertiary bromocarboxylic  
34  
35 acid, also likely proceeding via a carbocation intermediate.<sup>25</sup> Interestingly, other azide sources  
36  
37 such as sodium azide or tetrabutylammonium azide showed no reaction, suggesting TMSN<sub>3</sub> is  
38  
39 required for the reaction to proceed. Though fruitless towards the synthesis of manzacidin A, this  
40  
41 chemistry is currently under further synthetic and mechanistic investigations.

Based on the above foray, we realized the strategic benefit of using a pre-functionalized substrate for the enzymatic hydroxylation in improving the step efficiency of our synthesis. Specifically, early installation of the  $\gamma$  C–N bond in the synthesis would avoid subsequent concession steps, including the tethering strategy for a stereospecific intramolecular C–H amination. The proposed strategy would also dovetail nicely with GriE-mediated  $\delta$  hydroxylation, which based on our substrate scope model accepts substrates with additional substitution at the  $\gamma$  position. This strategy is not without its challenge, as methods to effect direct C–H amination on unprotected AAs are not well-established. However, Britton's recent work on the  $\gamma$  selective C–H fluorination of unprotected L-Leu with tetrabutylammonium decatungstate (TBADT) as photocatalyst served as an inspiration to develop an analogous protocol for amination.<sup>26</sup> In the proposed catalytic cycle,<sup>27</sup> TBADT selectively performs hydrogen atom abstraction on the substrate to generate a persistent tertiary carbon centered radical. Subsequent trapping of this species by N-fluorobenzesulfonimide (NFSI) results in C–F

1  
2  
3 bond formation at the  $\gamma$  position. We reasoned that a similar electrophilic azide source may prove  
4 amenable to form our desired C–N bond.<sup>10b,17a,b</sup> Indeed, when L-Leu•TFA was stirred with 5  
5 mol% TBADT and 3 equiv. of azide **15**, azidoleucine **16** was obtained; albeit as a 1:2.5 SM:PD  
6 mixture, which was separated by preparative HPLC (Scheme 3A). This reaction proved scalable,  
7 resulting in 49% yield using 500 mg of L-Leu•TFA (SM was not recovered). This is the first  
8 example of TBADT mediated azidation, as well as the first C–H azidation protocol on  
9 unprotected AAs. Due to the unique reactivity of the catalytic manifold, extension of this  
10 photoreaction is currently under further investigation in our group. Biocatalytic hydroxylation of  
11 **16** with GriE yielded difunctionalized amino acid **17** in >95% conversion on 130 mg scale. This  
12 sequence is remarkable, as two sequential C–H functionalizations on unprotected L-Leu could be  
13 effected. At this stage, **17** was Boc protected and lactonized to **18** in 58% yield over two steps.  
14 All that remained was a simple reduction and Boc protection to finish our synthesis. To our  
15 surprise, submitting **18** to reductive conditions ( $H_2/PtO_2$ ) resulted in complete conversion to  
16 lactam **19** in 55% yield. A quick literature search revealed that the same by-product was  
17 previously obtained during reduction of a structurally similar nitrolactone.<sup>28</sup> Presumably, after  
18 azide reduction the molecule can adopt a pseudo boat conformation, which allows the tertiary  
19 amine to participate in an intramolecular addition-elimination with the lactone carbonyl to afford  
20 **19**. This pathway also occurred in the presence of triphenylphosphine ( $PPh_3$ ), presumably  
21 through a Staudinger reaction. No desired product was ever formed, even when the reaction was  
22 run in the presence of  $Boc_2O$  or Boc-ON to capture the transiently formed amine after reduction.  
23 Though **19** was considered to complete the synthesis of manzacidin C via Boc protection and  
24 methanolysis, it would only improve our previous synthesis by one step. Nevertheless, the facile  
25 lactamization provided a key insight to choreograph an alternative sequence to access **5** from **17**

(Scheme 3B). We reasoned that under basic pH, the carboxylic acid would exist as the carboxylate, which would have a much-reduced propensity to undergo lactamization during the azide reduction and Boc protection sequence. Thus, a one-pot procedure was developed wherein **17** was first reduced, the resulting free amines (**20**) subsequently Boc protected, and alcohol/carboxylic acid motifs lactonized to provide **5** in 41% yield over two steps. This constitutes a five-step formal synthesis of manzacidin C in 11% overall yield. Although displaying equivalent overall yield to our first generation synthesis, it is remarkably shorter and displays significantly improved ideality over the first three transformations.

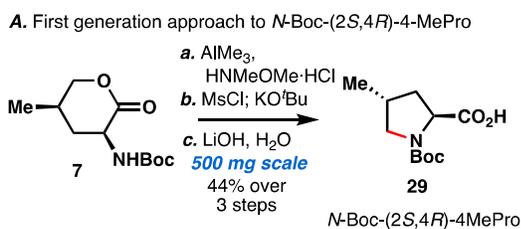

**Scheme 4.** Synthetic access to complex pyrrolidine scaffolds starting from lactone **7**.

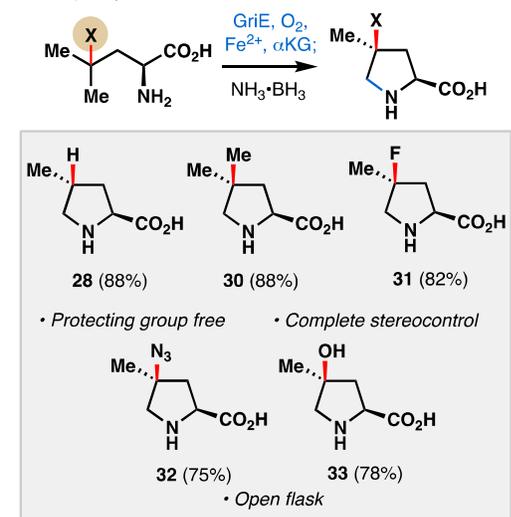

During the course of our studies, we also sought to demonstrate the utility of GriE in the synthesis of other complex and biologically relevant molecules (Scheme 4). Since hydroxylated AAs are prevalent in nonribosomal peptides (NRPs), **7** was submitted to a peptide coupling by simple heating with L-glycine ethyl ester (**21**) to provide dipeptide **22** in excellent yield.<sup>29</sup> Standard peptide coupling requires the use of carboxylic acid activating agents, whereas lactones

1  
2  
3 represent a form of protected and pre-activated carboxylic acids, obviating the use of external  
4 coupling reagents. Lactone **7** was converted to the piperidyl amide, followed by Parikh-Doering  
5 oxidation to yield hemiaminal **23**. This functionalized proline variant features increased  
6 oxidation state at the  $\delta$  position, serving as a handle for further derivatization. Synthetic  
7 manipulation of similarly oxidized pyrrolidines—albeit lacking methylation at the  $\delta$  position—  
8 has recently been reported in the literature.<sup>30</sup> To demonstrate this, **23** was reacted with  
9 allyltrimethylsilane (**24**) in the presence of  $\text{BF}_3 \cdot \text{Et}_2\text{O}$  to yield **25** in 49% yield as a 4:1 mixture of  
10 diastereomers.<sup>31</sup> Carbapenam  $\beta$ -lactams represent structurally intricate scaffolds *en route* to  
11 carbapenam antibiotics.<sup>13b</sup> Since hemiaminal **23** exists in an equilibrium with the free aldehyde,  
12 Horner-Wadsworth-Emmons (HWE) reaction yielded a mixture of the homologated pyrrolidine  
13 (**S-03**) and its open chain tautomer (**S-04**) (Figure S3).<sup>30a</sup> Submitting the mixture directly to  
14 trifluoroacetic acid resulted in complete conversion to the corresponding amino acid (**S-05**) in  
15 63% yield over two steps. Dehydration with Mukaiyama reagent (2-chloro-1-methylpyridinium  
16 iodide) afforded  $\gamma$ -methylated carbapenam **27** in 41% yield as a 5:1 mixture of diastereomers.<sup>32</sup>

B. One-pot synthesis 4-MePro derivatives

Due to the ubiquity of (2*S*,4*R*)-4-MePro (**28**) in a variety of biologically interesting NRPs, a scalable and efficient synthesis of this motif is highly desirable.<sup>13-15</sup> A previous approach to **28** requires an alcohol directing group and uses expensive Crabtree's catalyst to perform asymmetric reduction of an exocyclic olefin, yielding the desired stereochemistry with 40:1 dr.<sup>33</sup> Towards (2*S*,4*R*)-4-MePro, **7** was converted to the Weinreb amide as previously described (*vide supra*). The resulting alcohol was then mesylated and cyclized in one-pot upon addition of  $\text{KO}^t\text{Bu}$ . Hydrolysis of the Weinreb amide with  $\text{LiOH}$  provided Boc-(2*S*,4*R*)-4-MePro (**29**) in 44% over three steps on 500 mg scale and 30% overall yield from L-Leu (Scheme 5A). Our synthesis compares favorably to the hydrogenation route as it proceeds with complete stereocontrol and avoids directing groups and expensive catalysts. An observation during our substrate scope examination of GriE spurred further work in this area. It was observed that hydroxylation of  $\gamma$ -Me-L-Leu with GriE resulted in minor amounts of over oxidation to an

1  
2  
3 aldehyde, which is present in solution as the cyclic imine. This was similarly observed with L-  
4  
5 Leu as well as other  $\gamma$ -substituted L-Leu variants with increased enzyme loading. Drawing  
6  
7 inspiration from (2*S*,4*R*)-4-MePro's biosynthesis (see Supporting Information), we reasoned that  
8  
9 conducting the reaction with sufficiently high GriE concentration, followed by addition of a mild  
10  
11 reductant could yield  $\gamma$ -substituted L-Pro derivatives in a single step (Scheme 5B).<sup>34</sup> To our  
12  
13 delight, this chemoenzymatic cascade could be performed on L-Leu and its derivatives—  
14  
15 commercially available or synthesized from L-Leu in one step utilizing TBADT mediated  
16  
17 photochemistry or Gox hydroxylation—, resulting in five unique proline derivatives in one step.

## 24 **Conclusion**

25  
26  
27  
28  
29 During the course of this work we demonstrated the unique advantage of combining  
30  
31 enzymatic and traditional chemical methods in complex molecule synthesis.<sup>8b</sup> Our initial  
32  
33 attempts to emulate the biogenesis of manzacidin C in the laboratory resulted in the  
34  
35 characterization of a leucine hydroxylase, GriE, that can be used for preparative scale  
36  
37 hydroxylation of a wide range of AAs. Additionally, our efforts to address the construction of the  
38  
39 quaternary center of the target molecule yielded interesting new methodologies for nucleophilic  
40  
41 opening of lactones with azides and photocatalytic C–H azidation of unprotected AAs. These  
42  
43 discoveries culminated in an efficient formal synthesis of manzacidin C in just five steps. We  
44  
45 further demonstrated the synthetic utility of amino acid oxidation with GriE by developing a  
46  
47 chemoenzymatic approach to a variety of structurally and biologically interesting molecules,  
48  
49 including novel proline analogs. Further applications of this synthetic paradigm<sup>35</sup> in the  
50  
51 preparation of bioactive natural products are on-going and will be reported in due course.

## Experimental Procedures

Compounds **5**, **6**, **7**, **10**, **12**, **15**, **16**, **17**, **20**, **22**, **28**, **30**, **31**, **32**, and **33** were previously synthesized and characterized.<sup>9a</sup>

### ***tert*-butyl ((2*S*,4*R*)-5-(carbamoyloxy)-1-(methoxy(methyl)amino)-4-methyl-1-oxopentan-2-yl)carbamate (**8**)**

A flame-dried 100 mL round bottom (w/ stir bar) was sequentially charged with *N,O*-dimethylhydroxylamine hydrochloride (1.21 g, 12.44 mmol, 3.0 eq) and 12.4 mL anhydrous THF. The suspension was stirred under Ar and cooled to 0 °C using an ice bath. AlMe<sub>3</sub> (2 M in PhMe, 6.2 mL, 12.44 mmol, 3.0 eq) was added via syringe pump over 30 min. The resulting solution was stirred for 1h at 23 °C, then cooled to –30 °C using a dry ice/acetone bath. Lactone **7** (0.951 g, 4.14 mmol, 1.0 eq, 0.5 M in THF) was added to a dry scintillation vial and dissolved in anhydrous THF (8.3 mL). The resulting solution was added dropwise over 10 min to the round bottom at –30 °C. After 30 min, the reaction was then quenched at –30 °C with 20 mL 10% (w/w) aq. Rochelle's salt (20 mL) and Et<sub>2</sub>O (20 mL). The resulting mixture was allowed to stir at 23 °C for 30 min, diluted with H<sub>2</sub>O and filtered over celite. The aq. layer was then extracted with Et<sub>2</sub>O (3 x 20 mL). The organics were washed with sat. aq. NaCl (50 mL), dried over MgSO<sub>4</sub>, filtered, and concentrated by air stream. The resulting oil was immediately transferred to a 250 mL round bottom flask, placed under Ar, and diluted with anhydrous DCM (83 mL). This solution was cooled to –40 °C, and trichloroacetyl isocyanate (740 μL, 6.22 mmol, 1.2 eq) was added dropwise with stirring. The reaction was stirred for 30 min at this temperature, then warmed to 23 °C and concentrated *in vacuo*. The resulting oil was diluted with MeOH (56 mL) and K<sub>2</sub>CO<sub>3</sub> (860 mg, 6.22 mmol, 1.5 eq) was added. The resulting slurry was stirred for 30 min, filtered over celite, and concentrated *in vacuo*. The crude oil was purified by silica gel

26 Two 20 mL Biotage<sup>®</sup> microwave vials were flame dried (w/ stir bars). To each vial was added  
27 225  $\mu\text{L}$  of 1 M stock solution of **8** in DCM. The vials were placed on high vacuum for 30 min,  
28 resulting in immediate formation of a yellow foam. After refilling with Ar, the vials were moved  
29 to a glovebox, wherein AgOTf (35 mg, 0.18 mmol, 0.25 eq), bathophenanthroline (0.182 g, 0.55  
30 mmol, 0.5 eq), and anhydrous/degassed MeCN (4 mL) was added to each vial. The vials were  
31 covered with foil and stirred for 30 min. Subsequently, 4 mL MeCN and PIDA (0.182 g, 0.55  
32 mmols, 1.0 eq) were added to each vial. Each vial was sealed, wrapped in foil, removed from the  
33 glovebox, and heated to 82  $^\circ\text{C}$  (with stirring) in an oil bath for 24 h. The reactions were cooled to  
34 23  $^\circ\text{C}$ , combined, filtered over a plug of silica with EtOAc, and concentrated *in vacuo*. The  
35 resulting crude material was purified by silica gel chromatography via gradient elution (1:1  
36 EtOAc:hexanes to EtOAc), affording **8** (22 mg, 12% yield) and **9** (0.117 g, 65%, white solid).  $^1\text{H}$   
37 NMR (400 MHz,  $\text{CDCl}_3$ ):  $\delta$  6.11 (s, 1H), 5.46 (d,  $J = 9.0$  Hz, 1H), 4.81 (t,  $J = 9.7$  Hz, 1H), 4.11

14 Carbamate **9** (0.104 g, 0.31 mmol, 1.0 eq) was added to a scintillation vial (w/ stir bar) and  
15 dissolved in 3.1 mL THF (0.1M) with stirring. The solution was subsequently treated with TEA  
16 (174  $\mu\text{L}$ , 1.25 mmol, 4.0 eq), DMAP (76 mg, 0.62 mmol, 2.0 eq), and  $\text{Boc}_2\text{O}$  (0.273 g, 1.25  
17 mmol, 4.0 eq). After stirring 1.5 h, the reaction was quenched with sat. aq.  $\text{NH}_4\text{Cl}$  (3.0 mL),  
18 extracted with EtOAc (3 x 10 mL), and washed with sat. aq. NaCl. The organics were dried over  
19  $\text{MgSO}_4$ , filtered, and concentrated *in vacuo*. The resulting material was diluted with 6.3 mL  
20 MeOH (0.05 M), cooled using an ice bath (0 °C), and  $\text{K}_2\text{CO}_3$  (86 mg, 0.62 mmol, 2.0 eq) was  
21 added. The resulting slurry was warmed to 23 °C and stirred for 12 h. After concentrating *in*  
22 *vacuo*, the mixture was dissolved in 10 mL  $\text{H}_2\text{O}$  and 10 mL EtOAc. The pH of this mixture was  
23 adjusted to 3 using AcOH. The aq. layer was extracted with EtOAc (3 x 10 mL) and  
24 concentrated *in vacuo*. The resulting oil was diluted with 10 mL PhMe.  $\text{MgSO}_4$  (~0.5 g) was then  
25 added, and the resulting slurry was stirred vigorously with heating for 2 h at 70 °C using an oil  
26 bath. The slurry was cooled to 23 °C, filtered, and concentrated *in vacuo*. The resulting crude  
27 material was purified by silica gel chromatography via gradient elution (dry loaded) (2:98  
28 MeOH:DCM to 5:95 MeOH:DCM), affording **5** (54 mg, 50% yield) as a white solid.  $^1\text{H}$  NMR  
29 spectrum matches previous report.<sup>9a</sup>  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ ):  $\delta$ . 5.30 (bs, 1H), 4.71 (bs, 1H),

**(S)-N-(5,5-dimethyl-2-oxotetrahydrofuran-3-yl)benzamide (13)**

Following previously reported procedure,<sup>9a</sup> *E. coli* expressing Gox were grown on 400 mL scale. After harvest, the cells were resuspended to OD<sub>600</sub> = 45 in 50 mM kPi buffer (pH 7.0). Cells were disrupted by sonication (3x1 min, 50% duty cycle) and pelleted by centrifugation at 4,000 rpm for 15 min at 4 °C. A 250 mL Erlenmeyer flask was charged with L-leucine (328 mg, 2.5 mmol, 1.0 equiv), L-ascorbic acid (440 mg, 2.5 mmol, 1.0 equiv), α-ketoglutaric acid (disodium salt dihydrate, 1.69 g, 7.5 mmol, 3.0 equiv), and FeSO<sub>4</sub> (heptahydrate, 28 mg, 0.1 mmol, 0.04 equiv). After addition of clarified Gox lysate (50 mL), the flask was shaken at 20 °C for 7 h at 250 rpm. Reaction was quenched by addition of 1 M HCl (20 mL) and centrifuged at 4,000 rpm for 15 min at 4 °C. The supernatant was collected and concentrated to dryness and was used without further purification. The crude material was resuspended in sat. aq. NaHCO<sub>3</sub> (~ 75 mL). To this suspension was added a solution of BzCl (1.16 mL, 10 mmol, 4.0 equiv) in 75 mL DCM and the mixture was stirred vigorously at room temperature overnight. The pH of the mixture was adjusted to 2–3 and the layers were separated. The aqueous phase was extracted with DCM (2 x 50 mL), and the combined organic layers were washed with sat. aq. NaCl (50 mL), dried over MgSO<sub>4</sub>, and concentrated *in vacuo*. The resulting crude material was purified by silica gel chromatography via gradient elution (1:4 EtOAc:hexanes to 1:1 EtOAc:hexanes) to afford lactone **13** (269 mg, 46% yield over 2 steps) as a white solid. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>): δ 7.80 (d, *J* = 7.2, 2H), 7.55 (d, *J* = 7.3 Hz, 1H), 7.45 (t, *J* = 7.6 Hz, 2H), 6.63 (s, 1H), 4.92 (ddd, *J* = 11.7, 8.7, 5.4 Hz, 1H), 2.90 (dd, *J* = 12.6, 8.6 Hz, 1H), 2.08 – 1.97 (t, *J* = 12.6 Hz, 1H), 1.56 (s, 6H); <sup>13</sup>C NMR (101 MHz, CDCl<sub>3</sub>): δ 175.4, 167.7, 133.1, 132.2, 128.7, 127.2, 83.4, 50.8, 42.5, 29.1, 27.1; R<sub>f</sub> =

0.40 (1:1 EtOAc:hexanes);  $[\alpha]_D^{20} = 47.0^\circ$  ( $c = 0.3$ ,  $\text{CHCl}_3$ ); mp = 121 °C; HRMS (ESI-TOF) m/z:  $[\text{M}+\text{H}]^+$  Calcd for  $\text{C}_{13}\text{H}_{15}\text{NO}_3\text{H}^+$  234.1130; Found 234.1121.

**(S)-4-azido-2-benzamido-4-methylpentanoic acid (14)**

To a flame-dried 10 mL round bottom flask (w/ stir bar) under Ar, was added **13** (30 mg, 0.13 mmol, 1.0 eq). The flask was charged with 220  $\mu\text{L}$   $\text{MeNO}_2$  and 220  $\mu\text{L}$   $\text{TMSN}_3$  (both dried over 4Å molecular sieves prior to use). The resulting solution was treated dropwise with anhydrous  $\text{SnCl}_4$  (1 M in heptane) (424  $\mu\text{L}$ , 0.42 mmol, 3.3 eq) at 0 °C. The reaction was stirred at 0 °C for 1 h, immediately warmed to 23 °C, and stirred at this temperature for 48 h. The reaction was diluted with 1 mL EtOAc and quenched with 1 mL  $\text{H}_2\text{O}$  with vigorous stirring. The resulting solution was adjusted to pH = 1 using 1 N aq. HCl. The aq. layer was extracted with EtOAc (3 x 5 mL) and the combined organics were washed with sat. aq. NaCl, dried over  $\text{MgSO}_4$ , filtered, and concentrated *in vacuo*. The resulting crude oil was then purified by silica gel chromatography (1:1 EtOAc:hexanes, then gradient elution 1:99 MeOH:DCM 1% AcOH to 3:97 MeOH:DCM 1% AcOH), affording **14** (29 mg, 82% yield) as a yellow oil.  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ ):  $\delta$  7.86 – 7.78 (m, 2H), 7.59 – 7.50 (m, 1H), 7.46 (dd,  $J = 8.4, 6.9$  Hz, 2H), 7.27 (s, 1H), 4.75 (ddd,  $J = 9.9, 6.2, 4.2$  Hz, 1H), 2.20 – 1.99 (m, 2H), 1.43 (d,  $J = 19.3$  Hz, 6H);  $^{13}\text{C}$  NMR (101 MHz,  $\text{CDCl}_3$ ):  $\delta$  176.7, 175.3, 168.2, 133.1, 132.4, 128.9, 127.3, 60.9, 51.1, 41.6, 27.2, 25.3, 20.8;  $R_f = 0.15$  (5:95 MeOH:DCM 1% AcOH);  $[\alpha]_D^{20} = -11.8^\circ$  ( $c = 0.3$ ,  $\text{CHCl}_3$ ); HRMS (ESI-TOF) m/z:  $[\text{M}+\text{H}]^+$  Calcd for  $\text{C}_{13}\text{H}_{16}\text{N}_4\text{O}_3\text{H}^+$  277.1301; Found 277.1300.

***tert*-butyl ((3*S*,5*S*)-5-azido-5-methyl-2-oxotetrahydro-2*H*-pyran-3-yl)carbamate (18)**

1  
2  
3 A scintillation vial was charged with 4-azidoleucine (TFA salt, 22 mg, 0.08 mmol, 1.0 equiv), L-  
4 ascorbic acid (7.0 mg, 0.04 mmol, 0.5 equiv),  $\alpha$ -ketoglutaric acid (disodium salt dihydrate, 18  
5 mg, 0.08 mmol, 1.0 equiv), followed by 4.0 mL of 50 mM kPi buffer (pH 7.5). After addition of  
6  
7  
8 20  $\mu$ L of 200 mM aq. FeSO<sub>4</sub> solution (4.0  $\mu$ mol, 0.05 equiv), the reaction was started by the  
9  
10 addition of GriE stock solution (final concentration = 0.015 mM, 0.00075 equiv). The mixture  
11  
12 was shaken at 20 °C, 250 rpm. After 2 h, L-ascorbic acid (7.0 mg, 0.04 mmol, 0.5 equiv),  $\alpha$ -  
13  
14 ketoglutaric acid (disodium salt dihydrate, 18 mg, 0.08 mmol, 1.0 equiv), 20  $\mu$ L of 200 mM aq.  
15  
16 FeSO<sub>4</sub> solution (4.0  $\mu$ mol, 0.05 equiv), and GriE stock solution ( 0.00075 equiv) were added and  
17  
18 the mixture was shaken further for 3 h. The reaction was acidified with 1 M HCl (1 mL) and  
19  
20 centrifuged at 15,000 rpm for 15 min. The supernatant was collected and lyophilized. The  
21  
22 resulting off-white powder was treated with 2 M NaOH until pH ~ 9.0 and H<sub>2</sub>O was added to  
23  
24 adjust the volume to ~ 2.5 mL. To this suspension was added a solution of Boc<sub>2</sub>O (61 mg, 0.28  
25  
26 mmol, 3.5 equiv) in 2.5 mL EtOH and the mixture was stirred at room temperature overnight.  
27  
28 The pH of the solution was adjusted to 2–3 and the mixture was concentrated *in vacuo* to remove  
29  
30 EtOH. To the resulting brown slurry was then added DCM (4 mL) and the mixture was stirred  
31  
32 overnight at room temperature. The layers were separated, the aqueous phase was extracted with  
33  
34 DCM (2 x 2 mL), and the combined organic layers were washed with sat. aq. NaCl (5 mL), dried  
35  
36 over MgSO<sub>4</sub>, and concentrated *in vacuo*. Purification by silica gel chromatography (1:5 to 1:1  
37  
38 EtOAc:hexanes) afforded lactone **18** (12.5 mg, 58% yield over 2 steps) as a white solid. <sup>1</sup>H NMR

### 2-((3*R*,5*S*)-3-methyl-5-(piperidine-1-carbonyl)pyrrolidin-2-yl)acetic acid (**S-05**)

To a flame-dried 10 mL round bottom flask under Ar (w/ stir bar) was added NaH (22 mg, 0.55 mmol, 2.0 eq) followed by 3.0 mL anhydrous THF (0.2M). *tert*-Butyl diethylphosphonoacetate (130 μL, 0.55 mmol, 2.0 eq) was added dropwise, and the resulting solution was stirred for 1 h. Amide **23** (86 mg, 0.27 mmol, 1.0 eq) was added to a flame-dried scintillation vial and diluted with 550 μL anhydrous THF (0.1 M final concentration). The resulting solution was added to the round bottom flask dropwise. After stirring for 5 h, the reaction was quenched with sat. aq. NH<sub>4</sub>Cl (2 mL). The resulting mixture was diluted with 10 mL EtOAc. The aq. layer was extracted with EtOAc (3 x 5 mL). The organics were then washed with sat. aq. NaCl, dried over MgSO<sub>4</sub>, filtered, and concentrated *in vacuo*. The crude oil was then dissolved in 800 μL DCM (0.3M). The solution was cooled to 0 °C using an ice bath, and treated with 270 μL TFA (1.0 M final TFA concentration). The reaction was heated at 80 °C using an oil bath for 12 h. The reaction was concentrated *in vacuo* and purified using Dowex 50WX8 resin (5 grams). The resin was charged with 1 N HCl (until pH = 1) and washed with H<sub>2</sub>O (until pH = 6–7). The crude material was added to the resin in H<sub>2</sub>O, washing with MeCN then H<sub>2</sub>O. 1 N NH<sub>4</sub>OH was then used to wash the resin until **S-05** eluted completely as judged by TLC (Note: TLC plates were run in 2:8 DCM:MeOH and dried for 1 min to remove NH<sub>4</sub>OH prior to staining with ninhydrin). The fractions were concentrated *in vacuo* affording **S-05** (44 mg, d.r. = 1.7:1.0, 63% over two steps) as a white solid. <sup>1</sup>H NMR (400 MHz, CD<sub>3</sub>OD): δ 4.75 (dd, *J* = 9.7, 6.4 Hz, 2H), 4.70 – 4.61 (m, 1H), 3.96 (dt, *J* = 9.6, 5.7 Hz, 1.6H), 3.67 – 3.51 (m, 6H), 3.45 (t, *J* = 5.7 Hz, 5H), 2.71

20  
21 To a flame-dried 10 mL round bottom flask (w/ stir bar) under Ar was added 2-chloro-1-methyl-  
22 pyridinium iodide (Mukaiyama reagent) (0.119 g, 0.47 mmol, 4.0 eq), 1.5 mL anhydrous MeCN,  
23 and TEA (130  $\mu\text{L}$ , 0.93 mmol, 8 eq). The mixture was heated to 70 °C in an oil bath with stirring  
24 for 30 min. To a second flame-dried 10 mL round bottom flask (w/ stir bar) under Ar was added  
25 **S-05** (29.6 mg, 0.12 mmol, 1.0 eq) and 1.5 mL anhydrous MeCN. The resulting solution was  
26 subsequently heated to 70 °C in an oil bath with stirring for 30 min. The solution from the first  
27 round bottom flask was taken up in a syringe and added to the second round bottom flask  
28 dropwise. The first round bottom flask was rinsed with 3 mL anhydrous DCM, and the resulting  
29 solution was added dropwise to the second round bottom flask. After 15 min, the reaction was  
30 gradually cooled to 23 °C by turning off the heat but leaving the reaction in the oil bath. After  
31 stirring for 16 h, the reaction was concentrated *in vacuo*. The resulting oil was dilute with 10 mL  
32 EtOAc and 10 mL sat. aq. NaCl. The aq. layer was extracted with EtOAc (3 x 5 mL). The  
33 organics were then washed with sat. aq. NaCl, dried over  $\text{MgSO}_4$ , filtered, and concentrated *in*  
34 *vacuo*. The resulting crude material was purified by silica gel chromatography using gradient  
35 elution (6:4 EtOAc:hexanes to 7:3 EtOAc:hexanes), affording **27** (11 mg, d.r. = 5.0:1.0, 41%) as

Calcd for  $\text{C}_{13}\text{H}_{20}\text{N}_2\text{O}_2\text{H}^+$  237.1603; Found 237.1577.

**(2*S*,4*R*)-1-(*tert*-butoxycarbonyl)-4-methylpyrrolidine-2-carboxylic acid (29)**

To a flame-dried 50 mL round bottom flask under Ar (w/ stir bar) was added *N,O*-dimethylhydroxylamine hydrochloride (0.64 g, 6.56 mmol, 3.0 eq) and 6.6 mL anhydrous THF. The suspension was cooled to 0 °C using an ice bath and  $\text{AlMe}_3$  (2 M in PhMe, 3.3 mL, 6.56 mmol, 3.0 eq) was added via syringe pump over 30 min. The resulting solution was stirred for 1h at 23 °C, then cooled to –30 °C using a dry ice/acetone bath. Lactone **7** (0.501 g, 2.19 mmol, 1.0 eq) was added to a dry scintillation vial, diluted with 4.3 mL anhydrous THF (0.5M), and added dropwise over 10 min to the 50 mL round bottom at –30 °C. After stirring 30 min, the reaction was then quenched at –30 °C with 20 mL 10% (w/w) aq. Rochelle's salt (20mL) and  $\text{Et}_2\text{O}$  (20mL). The resulting mixture was allowed to stir at 23 °C for 30 min, diluted with  $\text{H}_2\text{O}$  and filtered over celite. The aq. layer was then extracted with  $\text{Et}_2\text{O}$  (3 x 20 mL). The organics were washed with sat. aq. NaCl (50 mL), dried over  $\text{MgSO}_4$ , filtered, and concentrated by air stream.

1  
2  
3 The resulting oil was placed under Ar, dissolved in 22 mL anhydrous THF (0.1 M), and cooled  
4 to  $-78\text{ }^{\circ}\text{C}$  using a dry ice/acetone bath. After treating with TEA (610  $\mu\text{L}$ , 4.37 mmol, 2.0 eq) and  
5  
6 MsCl (186  $\mu\text{L}$ , 2.40 mmol, 1.1 eq), dropwise, the reaction was stirred for 1 h at  $-78\text{ }^{\circ}\text{C}$  then  
7  
8 allowed to warm to  $23\text{ }^{\circ}\text{C}$ . KO<sup>t</sup>Bu (1.23 g, 10.93 mmol, 5.0 eq) was then added, and the reaction  
9  
10 was allowed to stir 12 h. The reaction was filtered over celite and concentrated *in vacuo*. The  
11  
12 resulting material was diluted with 11 mL H<sub>2</sub>O (0.2 M final concentration) and treated with  
13  
14 LiOH (0.523 g, 21.85 mmol, 10.0 eq). The resulting slurry was heated to  $80\text{ }^{\circ}\text{C}$  for 19 h. The  
15  
16 material was then filtered over celite. The aq. layer was extracted with Et<sub>2</sub>O and acidified to pH  
17  
18 = 1 using aq. HCl (1N). The solution was then extracted with DCM (3 x 20 mL). The organics  
19  
20 were washed with sat. aq. NaCl, dried over MgSO<sub>4</sub>, filtered, and concentrated *in vacuo*. The  
21  
22 resulting crude material was purified by silica gel chromatography using gradient elution (DCM  
23  
24 to 5:95 MeOH:DCM), affording **29** (0.222 g, 44% over three steps, mixture of rotamers) as a  
25  
26 slightly yellow oil. <sup>1</sup>H NMR (400 MHz, CD<sub>3</sub>OD):  $\delta$  4.31 – 4.20 (m, 2H), 3.64 (m, 2H), 3.31 (p,  $J$   
27  
28 = 1.7 Hz, 12H), 2.92 (m, 2H), 2.41 – 2.32 (m, 2H), 2.12 – 2.07 (m, 2H), 1.95 – 1.85 (m, 2H),  
29  
30 1.46 (s, 9H), 1.42 (s, 9H), 1.06 – 1.03 (m, 6H); <sup>13</sup>C NMR (101 MHz, CD<sub>3</sub>OD):  $\delta$  155.9, 81.4,

## 24 **Acknowledgments**

25  
26 Financial support for this work was generously provided by The Scripps Research Institute. We  
27  
28 thank C. A. Reiher and R. A. Shenvi for helpful discussions on tertiary lactone opening. We are  
29  
30 grateful to A. L. Rheingold, C. E. Moore, and M. Gembicky (University of California, San  
31  
32 Diego) for x-ray crystallographic analysis. We thank the Shen lab, the Disney lab, the Kodadek  
33  
34 lab, and the Roush lab for generous access to their instrumentations.
