Regioselective Synthesis of Calix[8]crowns by Direct Alkylation of *p-tert*-Butylcalix[8]arene

Corrada Geraci, Mario Piattelli and Placido Neri*

Istituto per lo Studio delle Sostanze Naturali di Interesse Alimentare e Chimico-Farmaceutico, C.N.R., Via del Santuario 110, I-95028 Valverde (CT), Italy

Abstract: Direct alkylation of *p*-tert-butylcalix[8]arene with oligoethylene glycol ditosylates affords calix[8]crowns-n with a bridging pattern dependent on the nature of the base used. Alkali metal hydrides (NaH or KH) afford mainly 1,4-calix[8]crowns 2_n in yield up to 46%, while K_2CO_3 and Cs_2CO_3 with triethylene glycol ditosylate give the 1,3-crown 4_4 and its 1,5-isomer 5_4 as the main product, respectively. Appreciable amounts of 1,2-calix[8]crowns 3_4 are formed with all bases but NaH. At room temperature the ¹H NMR spectra of compounds 2_n - 5_4 show broad signals indicative of hampered conformational mobility. Copyright © 1996 Elsevier Science Ltd

Among the variety of calixarene¹ derivatives synthesized in the last decade calixcrowns² undoubtedly occupy a prominent position due to their complexing properties toward several cations, often with very remarkable selectivity,³ leading to several practical applications.⁴ Although the greatest attention has been paid to calix[4]crowns, interesting results have recently been obtained also with calix[5]crowns⁵ and calix[6]crowns.⁶ Concerning calix[8]crowns, we have recently shown that the introduction of polyether chains in 1,3,5,7-tetra-*O*-benzylated derivatives originates compounds conformationally preorganized in the 220-415 K range.⁷ In that

study, preliminary attempts at the direct regioselective introduction of polyether chains in the parent *p-tert*-butylcalix[8]arene (1) had given unsatisfactory results.⁷ Further experiments have now allowed us to find that 1 reacts under appropriate conditions with oligoethylene glycol ditosilates to give the desired calix[8]crowns in satisfying yields.

chromatography in yield up to 46% (entries 1-2, Table 1).⁸ The reaction was extended to tetra- and pentaethylene glycol ditosylates to afford 1,4-calix[8]crown-n 2_5 and 2_6 in 31 and 25% yield respectively (entries 3-4, Table 1).⁸ The use of KH in place of NaH under identical conditions resulted in the formation of 1,2-calix[8]crown-4 3_4 (entry 5, Table 1), in addition to 2_4 .⁸ Weaker bases such as alkali metal carbonates required longer reaction time in order to give appreciable amounts of crowned calix[8]arenes. In fact, after 47 h the reaction using K₂CO₃ as a base afforded monotosylpolyether 6_4 in appreciable yields besides 1,2-crown 3_4 , while the main product was the 1,3-crowned calix[8]arene 4_4 (entry 6, Table 1).⁸ Cs₂CO₃ in similar conditions yields 1,5-isomer 5_4 as the main product (entry 7, Table 1).⁸

Structure for assignment compounds 2_n relied essentially on spectral analysis. Thus, the molecular masses were determined by FAB(+) mass spectroscopy, while the bridging pattern was inferred from extensive NMR analysis. At room temperature the ¹H NMR spectra of calix[8]crown 2_n show broad signals indicating that conformational motion is hampered. Thus, the spectrum of 2_4 at rt in (CD₃)₂CO shows broad, shapeless signals in the methylene region. The presence of four equal intensity signals at 1.17, 1.97, 1.22, and 1.25 ppm for the t-Bu groups is indicative of the presence in the molecule of a symmetry axis passing through two diametrical ArCH₂Ar groups.⁸ This was confirmed by the appearance in the ¹³C NMR spectrum of eight signals due to aromatic carbons bearing either an oxygen atom or a t-Bu-group (140-155 ppm region), as well as two signals at δ 133.4 and 133.6 for the C-CH₂ carbons alkylated phenolic of rings.

Discrimination between the two possible bridging patterns (1,2 or 1,4) compatible with the observed symmetry was achieved by a combination of 2D HETCOR and long-range HETCOR NMR experiments performed in C_6D_6 at 310 K in order to have sufficiently resolved methylene signals. The presence of cross-peaks between the bridgehead aromatic carbons and two ArCH₂Ar singlets of 4 H intensity (δ 4.04 and 4.08) clearly indicated the 1,4-bridging. Structure assignment for the other 1,4-calix[8]crown 2₅ and 2₆ was based on similar arguments.

At this point the structure of 1,2-calix[8]crown-4 could be immediately assigned to 3_4 , that possesses the same symmetry as 2_4 (four 18 H singlets for *t*-Bu groups at 1.19, 1.20, 1.208, and 1.213 ppm are present in its ¹H NMR spectrum in (CD₃)₂CO, as well as eight signals for quaternary aromatic carbons are seen in the 140-155 ppm region of the ¹³C NMR spectrum).⁸ Interestingly, the chemical shift values for the three 2 H hydroxyl groups in the 1,2- and 1,4-isomers, 2_4 and 3_4 , are a sensitive structural probe. Indeed, in the spectrum of 2_4 these resonances appear at δ 8.35, 8.85, and 9.05, and are to be attributed respectively to a singly-H-bonded hydroxyl, a singly-H-bonded hydroxyl in a semicircular array and a doubly-H-bonded hydroxyl. In contrast, the spectrum of 3_4 contains a signal at δ 8.69, attributable to an OH single-H-bonded in a semicircular array, and two resonances at δ 8.97 and 9.13 for doubly-H-bonded OH groups.

Assignment of the bridging pattern to 1,3-calix[8]crown-4 44 was based on the presence of a symmetry element bisecting opposite aromatic rings, as indicated by its ¹H NMR spectrum which shows five singlets for t-Bu groups (δ 1.18, 1.23, 1.24, 1.26, and 1.27, 1:2:1:2:2) and by the presence in its ¹³C NMR spectrum of ten resonances in the 140-155 ppm region.⁸ Analogously the 1,5bridging in 5_4 was deduced from

Table 1. Yield of Calix[8]crown-n in Direct Alkylation of 1 with TsO(CH2CH2O)mTs (1 equiv)					
Entry	m	Base	Solvent	Time (h)	Compd (yield %)
1	3	NaH	THF/DMF	17	2 ₄ (46)
2	3	NaH	THF/DMF	3	2 ₄ (35)
3	4	NaH	THF/DMF	3	2 ₅ (31)
4	5	NaH	THF/DMF	3	2 ₆ (25)
5	3	КН	THF/DMF	17	2 ₄ (28), 3 ₄ (8)
6	3	K ₂ CO ₃	Me ₂ CO	47	3 ₄ (5), 4 ₄ (12), 6 ₄ (6)
7	3	Cs ₂ CO ₃	Me ₂ CO	22	2 ₄ (2), 3 ₄ (6), 5 ₄ (13)

the presence of three t-Bu signals in its ¹H NMR spectrum (δ 1.24, 1.32, and 1.35, 2:1:1) and six quaternary carbon resonances in the low-field ¹³C NMR region.⁸

The regiochemical outcome observed in the alkylation of 1 with triethylenglycol ditosylate in the presence of various bases deserves a comment. We suggest that the major factor controlling the bridging position is the

strength of the base. Thus, in the presence of 6-10 equiv of a strong base (NaH or KH) the closure step of a mono-O-alkylcalix[8]arene like 6_4 reasonably proceeds through a well defined polyanion, very likely a 2,4,6,8-tetraanion of type 7, thus leading to 1,4-bridging. The reaction promoted by a weak base (K₂CO₃) proceeds through the formation of a monoanion in which, according to earlier observations,⁹ the charge is preferentially localized at position 3, so 1,3-bridged derivatives are preferentially formed. Cs₂CO₃, a base of intermediate strength, is unable to reach the same level of multiple deprotonation as does an alkali metal hydride and gives either a di- or a trianion, with a negative charge preferentially located at position 5. Cation

template effect can be invoked to explain the formation of 1,2-bridge with all bases but NaH.¹⁰ In any case, definite conclusions have to await a more systematic study extended to polyethylene glycols of different length.

The direct regioselective synthesis of calix[8]crowns here described provides a convenient method for the intrabridging of the calix[8]arene macrocycle with different bridging patterns. It is conceivable that a careful extension of this methodology could lead to multiple-crowned calix[8]arenes effectively preorganized to host suitable guests. Moreover, the succession of two or more steps in different conditions should lead to mixed bridging patterns with interesting stereochemical implications.
