Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

Changes in the Key Odorants and Aroma Profiles of Hamlin and Valencia Orange Juices not from Concentrate (NFC) During Chilled Storage

1 **ABSTRACT.** Application of the aroma extract dilution analysis (AEDA) on the vola-
2 tiles isolated by extraction/SAFE distillation from NFC (not from concentrate) juice
3 from Hamlin oranges revealed 51 odor-active constituents in the flavor dilution (FD)
4 factor range of 8 to 8192 among which vanillin, wine lactone and (R)-linalool ap-
5 peared with the highest FD factors. The AEDA applied on the volatile fraction of the
6 same batch of juice stored at 0 °C for ten months under aseptic conditions showed
7 clear changes in the aroma profile as well as in the FD factors of key odorants. The
8 reduction in the intensity of the citrus-like, pungent, green odor attributes in the aro-
9 ma profile correlated with the loss of 1-penten-3-one, acetaldehyde and (Z)-3-
10 hexenal and a clear decrease in hexanal, octanal, nonanal, decanal and (E,E)-2,4-
11 decadienal. Quantitation done by stable isotope dilution assays followed by a calcu-
12 lation of odor activity values (ratio of concentration to odor thresholds in citrate buffer)
13 confirmed that the quick loss of 1-penten-3-one and acetaldehyde already within a
14 few weeks, and a significant reduction in nearly all aldehydes over the storage time of
15 10 months was responsible for the changes in the overall aroma profile of the juice.
16 The same approach applied on Hamlin juice from the next harvest year as well as on
17 chilled stored NFC juice from Valencia oranges confirmed the results for another har-
18 vest year and another orange variety.

19

20 **KEY WORDS:** NFC orange juice, storage, aroma extract dilution analysis, stable iso-
21 tope dilution assay, odor activity value; 1-penten-3-one; acetic acid

22 INTRODUCTION

23 Orange trees (*Citrus sinensis*, L. Osbeck) are one of the oldest cultivated plants
24 and the fruit and juice production constantly increased due to the characteristic flavor
25 and beneficial nutrient content. Today, orange juice ranks among the world's most
26 produced fruit juices, and the per-capita-consumption in Germany was about 8 Liter
27 in 2014.¹ Two types of orange juices are prepared commercially; juice from concen-
28 trate (CJ) which undergoes a thermal treatment to evaporate the major part of the
29 water as well as the aroma fraction, and NFC (not from concentrate) juice, which is
30 only pasteurized and then chilled stored before consumption. Although freshly
31 squeezed orange juice is said to have a superior aroma compared to both, CJ and
32 NFC juice, in particular the overall aroma of NFC juices comes close to the aroma of
33 freshly squeezed juices.²

34 Investigations on the volatile fraction of orange juices were already started about
35 100 years ago,³ and until now more than 400 volatiles have been identified.⁴ Next to
36 (R)-limonene, (R)- α -pinene and myrcene, the esters (S)-ethyl 2-methylbutanoate,
37 ethyl butanoate and ethyl 2-methylpropanoate as well as the aldehydes (Z)-3-
38 hexenal, hexanal and acetaldehyde were previously characterized^{5,6} among the key
39 aroma compounds in freshly squeezed orange juice using the Sensomics concept.
40 But, the aroma of freshly squeezed orange juice is not stable, and a significant
41 change in the overall aroma profile rapidly occurs during processing and storage.⁷
42 For example, enzymatic reactions, thermal reactions during pasteurization and bot-
43 tling⁸⁻¹² are well-known to induce changes in the aroma composition.

44 In addition, several aroma compounds are newly formed or generated either dur-
45 ing storage in glass bottles in the trade or during chilled storage before bottling. Sev-
46 eral investigations have already been carried out to understand the formation of off-
47 flavors.^{7,9,13,14} Kirchner and Miller⁹ were among the first to study the changes in the

48 volatiles between fresh and stored juices and found an increase in, e.g. carvone, ace-
49 tic acid and α -terpineol, while esters, aldehydes and terpene hydrocarbons de-
50 creased. Tatum et al.¹³ later on suggested 2-methoxy-4-vinylphenol and 4-hydroxy-
51 2,5-dimethyl-3(2*H*)-furanone to be responsible for the aged off-flavor formed after
52 storage at 35 °C. Additionally, it is long known that the concentration of α -terpineol
53 increases significantly depending on the storage temperature.^{9,13-16}

54 However, most studies did not use approaches directly combining sensory evalua-
55 tion and analytical measurements, such as gas chromatography-olfactometry (GC-O)
56 or odor activity value calculations. In a first study trying to confirm the above men-
57 tioned compounds as marker substances for juice storage using the Sensomics con-
58 cept¹⁶ the authors did not confirm the influence of these compounds on the formation
59 of off-flavors during storage of juice from concentrate in glass bottles at 20 °C. In-
60 stead, a drastic decrease in acetaldehyde, octanal and decanal was found and it was
61 suggested that the increase in concentration of certain juice compounds together with
62 the decrease of key juice odorants is responsible for the overall changes in the aro-
63 ma of the orange juice during storage.¹⁶

64 But, to date, no comprehensive approach using the Sensomics concept including
65 systematic sensory experiments has been used to clarify the molecular reason for
66 changes in the overall aroma of chilled stored NFC orange juice. Therefore, it was
67 the aim of this study to clarify the molecular background of aroma changes occurring
68 during chilled storage of NFC orange juices from the two varieties, Hamlin and Va-
69 lencia, by means of the Sensomics concept. The particular focus was on compounds
70 degrading during storage in order to establish a basis for further studies on the path-
71 ways leading to their instability even under the mild conditions of a chilled storage.

72

73 MATERIALS AND METHODS

74 **Materials.** Orange juices were produced and stored by a commercial juice supplier
75 (Tropicana Products Inc). Fruits from the same batch of either Hamlin (Ham) or Va-
76 lencia (Val) oranges were extracted and stored in aseptic tanks at 0 °C. Samples
77 were taken every month for a total period of 10 months, filled in aseptic bottles, sent
78 frozen to Germany and stored at – 60 °C prior to analysis.

79 **Reference Odorants.** Reference compounds were obtained from the commercial
80 sources given in parentheses: acetaldehyde, (*E,E*)-2,4-decadienal, decanal, ethyl 2-
81 methylbutanoate, ethyl 3-hydroxyhexanoate, ethyl hexanoate, ethyl propanoate, hex-
82 anal, (*Z*)-3-hexenal, 4-hydroxy-2,5-dimethyl-3(*2H*)-furanone, 2-hydroxy-3-butanone,
83 3-isopropyl-2-methoxy-pyrazine, (*R*)-limonene, 3-(methylthio)propanal, methyl 3-
84 hydroxyhexanoate, 2- and 3-methylbutanoic acid, myrcene, (*E,Z*)-2,6-nonadienal,
85 octanal, 1-penten-3-one, phenylacetic acid, α -pinene, α -terpineol, vanillin and 2-ethyl-
86 3,5-methylpyrazine, 1,8-cineol, ethyl butanoate and linalool (Sigma-Aldrich Chemie,
87 Taufkirchen, Germany). Carvone, nootkatone, 1-octen-3-one and 2-methoxy-4-
88 vinylphenol (Lancaster, Mühlheim, Germany). Acetic acid and 2,3-butanedione
89 (Merck, Darmstadt, Germany). Nonanal and β -ionone (Roth, Karlsruhe, Germany).

90 The following reference odorants were synthesized as reported in the literature:
91 *trans*-4,5-epoxy-(*E*)-2-decenal¹⁷ and 3 α ,4,5,7 α -tetrahydro-3,6-dimethyl-2(*3H*)-
92 benzofuranone (wine lactone).¹⁸

93 **Chemicals** Ascorbic acid, citric acid (water free), ethanol, fructose, glucose, lithi-
94 um aluminium hydride, *trans*-p-menth-2-ene, potassium peroxomonosulfate, potassi-
95 um acetate, potassium ferrocyanide, sucrose, sodium thiosulfate, p-toluene sulfonic
96 acid and zinc sulfate were purchased from Sigma-Aldrich Chemie (Taufkirchen, Ger-
97 many). Aceton (suprasolv), acetic anhydride, methyl octanoate, silica gel, sodium
98 chloride, sodium hydrogen carbonate, anhydrous sodium sulfate, and sulfuric acid

99 were from Merck (Darmstadt, Germany). Diethyl ether and dichloromethane (Merck)
100 were freshly distilled before use.

101 **Isotopically Labeled Internal Standards.** These were synthesized as previously
102 reported: [$^2\text{H}_4$]-carvone and [$^2\text{H}_4$]- decanal,¹⁵ [$^2\text{H}_4$]-octanal,²⁰ [$^2\text{H}_6$]- α -terpineol,⁶ [$^2\text{H}_2$]-
103 linalool,²¹ [$^2\text{H}_3$]-(*E,E*)-2,4-decadienal,²² [$^2\text{H}_3$]-ethyl 2-methylbutanoate,²³ [$^2\text{H}_3$]-
104 vanillin,²⁴ [$^2\text{H}_3$]-ethyl hexanoate,²⁵ [$^2\text{H}_4$]-nonanal,²⁶ [$^2\text{H}_2$]-butanoic acid,²⁷ [$^2\text{H}_3$]- β -
105 ionone,²⁸ [$^{13}\text{C}_4$]-2,3-butanedione,²⁹ [$^2\text{H}_2$]-ethyl butanoate,³⁰ [$^2\text{H}_3$]-2-methoxy-4-vinyl-
106 phenol,³¹ [$^2\text{H}_4$]-(*Z*)-3-hexenal³² and [$^2\text{H}_4$]-hexanal.³³

107 Most of the syntheses were performed on a micro scale basis. Thus, concentra-
108 tions were determined by GC/FID as follows: An FID-response factor was calculated
109 by analyzing defined amounts of the respective unlabeled compound and methyl oc-
110 tanoate as internal standard. Using the same internal standard and the FID response
111 factor determined with the unlabeled compound, the concentration of the labeled
112 compound was calculated on the basis of a defined volume of the respective stock
113 solution.

114 [$^{13}\text{C}_2$]-Acetaldehyde, [$^2\text{H}_3$]-acetic acid, [$^{13}\text{C}_8$]-octanoic acid and [$^2\text{H}_2$]-1-penten-3-ol
115 were obtained from Sigma-Aldrich (Taufkirchen, Germany).

116 **Syntheses.**

117 *Synthesis of [$^2\text{H}_2$]-1-penten-3-one.* To obtain the target compound [$^2\text{H}_2$]-1-penten-
118 3-ol was oxidized with freshly prepared Dess Martin periodinane [1,1,1-triacetoxy-1,1-
119 dihydro-1,2-benziodoxol-3-(1*H*) one].

120 *Preparation of Dess Martin periodinane.*³⁴ 2-Iodobenzoic acid (40 mmol) and po-
121 tassium peroxomonosulfate (60 mmol) were suspended at 70 °C in distilled water
122 (300 mL) and stirred for 3 h. After cooling to 5 °C, the reaction mixture was stirred for
123 another 90 min. The white crystals formed were filtered off, washed with distilled wa-
124 ter (240 mL) followed by acetone (80 mL) and finally dried in a stream of nitrogen. A

125 mixture of the reaction product obtained (35 mmol), was refluxed with acetic acid an-
126 hydride (50 mL) and p-toluene sulfonic acid (0.6 mmol) for 2 h at 80 °C. After cooling
127 to 0 °C, the crystals formed were filtered off and washed with diethyl ether (50 mL).
128 Dess Martin periodinane was stored under argon prior to use.

129 *Oxidation of [²H₂]-1-penten-3-ol.* The alcohol (2.85 mmol in 10 mL anhydrous di-
130 chloromethane) was added within 10 min to a solution of Dess Martin periodinane
131 (3.42 mmol in 10 mL anhydrous dichloromethane), and the solution was stirred for 1
132 h at room temperature. Diethyl ether (50 mL) and an aqueous sodium thiosulfate-
133 solution (100 mL; 1 mol/L, saturated with sodium hydrogen carbonate) was added
134 and the reaction mixture was stirred for 10 min. The aqueous layer was separated
135 and extracted with diethyl ether (total volume: 90 mL). The combined organic layers
136 were subsequently washed with sodium thiosulfate (50 mL; 1 mol/L, saturated with
137 sodium hydrogen carbonate), an aqueous saturated sodium hydrogen carbonate so-
138 lution (100 mL) and finally with distilled water (100 mL). The solution was then dried
139 over sodium sulfate and the target compound was characterized by mass spectrome-
140 try.

141 **MS (EI):** *m/z* (%): 57 (100), 56 (92), 86 (83), 58 (50), 85 (46), 82 (21), 48 (15).

142 **MS (CI):** 87 (M+1, 100).

143 *Synthesis of [¹³C₈]-octanal.* The compound was prepared by reduction of ¹³C₈-
144 octanoic acid to [¹³C₈]-Octanol followed by an oxidation into the target compound us-
145 ing Dess Martin periodinane.

146 *Synthesis of [¹³C₈]-octanol.* [¹³C₈]-octanoic acid (0.7 mmol in 20 mL diethyl ether)
147 was slowly added to a solution of lithium aluminium hydride (0.6 mmol in 50 mL di-
148 ethyl ether) and the mixture was refluxed for 1 h. Ice water was slowly added until the
149 hydrogen formation stopped, and sulfuric acid (10%) was added dropwise to dissolve
150 the aluminium hydroxide formed. The aqueous layer was extracted with diethyl ether

151 (150 mL), the combined organic layers were washed with an aqueous saturated so-
152 dium chloride solution (50 mL) and finally dried over sodium sulfate.

153 *Synthesis of [¹³C₈]-octanal.* The alcohol was oxidized with Dess Martin periodinane
154 as described above for 1-penten-3-ol. To remove impurities, the aldehyde was puri-
155 fied by chromatography on silica gel using an n-pentane/diethyl ether gradient. The
156 [¹³C₈]-octanal was eluted with n-pentane/diethyl ether (9:1; 100 mL) and was charac-
157 terized by mass spectrometry.

158 **MS (EI):** *m/z* (%): 49 (100), 44 (68), 60 (66), 42 (33), 59 (30), 90 (16), 74 (15), 106
159 (4), 118 (2).

160 **MS (CI):** 136 (M+1, 100).

161 **Isolation of the Volatiles.** Orange juice (100 mL) was extracted with diethyl ether
162 (total volume: 200 mL) by vigorous stirring for 2 h, and the volatiles were isolated by
163 solvent assisted flavor evaporation (SAFE).³⁵ The distillate was separated into an
164 acidic fraction (AF) and a fraction containing the neutral/basic volatiles (NBF).³⁶ Each
165 fraction was concentrated at 40 °C to obtain a final volume of about 250 µL using a
166 Vigreux column (50 cm x 1.5 cm i.d.), and a micro distillation device.³⁷

167 **High Resolution Gas Chromatography/Olfactometry (HRGC/O), Aroma Ex-**
168 **tract Dilution Analysis (AEDA) and High Resolution Gas Chromatography/Mass**
169 **Spectrometry (HRGC/MS).** The SAFE distillates were injected by the cold on column
170 injector onto a GC column installed in a Carlo Erba Instruments gas chromatograph
171 HRGC 8000 (Hofheim, Germany). The volatiles were separated with a helium flow
172 rate of 1.9 mL per min on a J&W Scientific DB-FFAP column (30 m x 0.32 mm i.d.,
173 0.25 µm film thickness) (Folsom, USA) using the following parameters: 2 min held at
174 40 °C, then increased at 20 °C/min to 60 °C; held 2 min at 60 °C, then increased at 6
175 °C/min to 180 °C. Finally, the temperature was increased to 230 °C and held for 5
176 min. HRGC-O was performed by dividing the effluent 1:1 at the end of the capillary

177 column using a Y-shaped glass splitter (Chromatographie Handel Müller, Germany)
178 and two deactivated, non-coated fused-silica capillaries of 50 cm each. One was
179 connected with the flame ionization detector (250 °C) and the other with the sniffing
180 port (190 °C). The extract was diluted 1:1 until no odor-active compound could be
181 smelled. Thus, the flavour dilution factor indicates the last dilution in which an odorant
182 could be smelled.

183 The parameters used for the second column, a J&W Scientific DB 5 (30 m x 0.32
184 mm i.d., 0.25 µm film thickness) (Folsom, USA) were as follows: 2 min held at 40 °C,
185 then increased at 9 °C/min to 50 °C; held for 2 min and increased at 6 °C/min to 180
186 °C, Finally the temperature was increased at 9 °C/min to 240 °C and held for 5 min.

187 Linear retention indices (RI) of the compounds were calculated using a series of n-
188 alkanes (C6–C26 for DB-FFAP and C6–C18 for DB-5) as previously described.³⁶

189 HRGC/MS was performed by means of a Hewlett-Packard gas chromatograph
190 5890 series II (Waldbronn, Germany) connected to a Finnigan sector field mass
191 spectrometer type MAT 95 S (Bremen, Germany) using the capillaries described
192 above. Mass spectra were generated in the electron impact mode (MS-EI) at 70 eV
193 and in the chemical ionization mode (MS-CI) at 115 V using isobutane as the reac-
194 tant gas.

195 **Quantitation by Stable Isotope Dilution Assays.**

196 **Gas Chromatography/Ion Trap Mass Spectrometry (GC/ITMS).** Orange juice (5
197 to 1000 mL, depending on the concentration of the respective odorant determined in
198 preliminary experiments) was spiked with the respective isotopically labeled internal
199 standards either dissolved n-pentane or diethyl ether. The amount of the standard
200 was chosen in a similar concentration as the analyte, and the samples were equili-
201 brated for 30 min with stirring. After extraction with dichloromethane (10 to 1000 mL,
202 depending on the initial volume of the juice used), the volatiles and the labeled inter-

203 nal standards were isolated by SAFE distillation.³⁵ After drying over sodium sulfate
204 and concentration to about 200 μ L, the resulting solutions were analyzed by GC/MS.
205 Quantitation of major compounds was performed using a Varian 431 gas chromato-
206 graph (Darmstadt, Germany) equipped with the DB-FFAP column coupled to a Vari-
207 an mass spectrometer 220 (Darmstadt, Germany). Mass spectra were generated by
208 MS-CI using methanol as the reactant gas.

209 **Two dimensional High Resolution Gas Chromatography-Gas Chromatog-**
210 **raphy-Ion Trap-Mass Spectrometry (GCxGC/ITMS).** For the quantitation of trace
211 aroma compounds, two dimensional GCxGC/mass spectrometry was applied, using a
212 Thermo Finnigan Trace 2000 series gas chromatograph (Braunschweig, Germany)
213 equipped with a Fison Instruments moving capillary stream switching system (MCSS)
214 (Mainz-Kastel, Germany) and linked to a Varian CP 3800 gas chromatograph and a
215 Varian Saturn 2000 ion trap mass spectrometer (Darmstadt, Germany).

216 The samples were injected by the cold-on-column technique and after chromatog-
217 raphy on the first column (DB-FFAP), the odorant and the respective internal stand-
218 ard were cut out by means of the MCSS and transferred to the second column via a
219 heated transfer line. The effluent was condensed in a cold trap before the separation
220 was continued on the second column (DB-1701). The effluent was monitored by
221 means of the ion trap mass spectrometer in the CI-mode with methanol as reactant
222 gas. The heart cut time in the first dimension was determined using the respective
223 reference compound.³⁸ Response factors (R_f) were determined by analyzing mixtures
224 containing known amounts of the unlabeled target compound and the respective iso-
225 topically labeled internal standard in five different ratios (5:1, 3:1, 1:1, 1:3, and 1:5) by
226 either GC-MS or GCxGC/MS.

227 **Quantitation of Acetaldehyde.** Acetaldehyde was quantitated using an enzymatic
228 assay (Boehringer Mannheim/ R-Biopharm AG, Darmstadt, Germany) with photomet-

229 ric monitoring. The workup procedure and photometric measurements were carried
230 out according to the instruction manual using a 0.5 mL solution. To get rid of color
231 and proteins, orange juice (16g) was clarified with Carrez-I-solution (1 mL; potassium
232 ferrocyanide, 85 mM = 3.6 g $K_4[Fe(CN)_6] \times 3H_2O$ / 100 mL) and Carrez-II-solution (1
233 mL; zinc sulfate, 250 mM = 7.20 g $ZnSO_4 \times 7 H_2O$ / 100 mL) and the samples were
234 filled up in a 20 mL volumetric flask. The assay was calibrated with freshly distilled
235 acetaldehyde.

236 **Quantitation of Terpene Hydrocarbons.** The quantitation of the major terpene
237 hydrocarbons limonene, myrcene and α -pinene was carried out by HRGC-FID using
238 *trans*-p-menth-2-ene as the internal standard. For the quantitation of myrcene and α -
239 pinene 50 g of juice were used. The concentration of *trans*-p-menth-2-ene was cho-
240 sen between the expected concentrations of myrcene and of α -pinene. For limonene,
241 10 g juice were used. Extraction and SAFE distillation was done as described above.
242 The terpene hydrocarbons were enriched by silica column chromatography as fol-
243 lows: The concentrated distillate (1 mL) was placed on top of the glass column filled
244 with silica gel column in n-pentane, and the terpene hydrocarbons were eluted using
245 n-pentane. The solution was concentrated to 200 μ L and subjected to HRGC-FID.
246 Response factors were calculated from mixtures of known concentrations of *trans*-p-
247 menth-2-ene, limonene, myrcene and α -pinene.

248 **Sensory Evaluation. Aroma Profile Analysis.** Sensory analyses were carried out
249 in a sensory room designed for this purpose with individual sections for each panelist.
250 The room temperature was adjusted to 20 – 25°C, and to avoid any influence of col-
251 ored solutions, the evaluations were carried out in yellow tainted light. 20 panelists
252 were recruited from the German Research Center for Food Chemistry (Freising,
253 Germany), who were regularly trained in orthonasal odor perception.³⁹ The panelists
254 were asked to evaluate the intensity of the following odor attributes: pungent (1-

255 penten-3-one), green/grassy ((Z)-3-hexenal), orange/green (octanal), vanilla-like
256 (vanillin), citrus-like/flowery (linalool), clove-like (2-methoxy-4-vinylphenol), fruity
257 (ethyl butanoate), caramel-like (4-hydroxy-2,5-dimethyl-3(2H)-furanone), sour (acetic
258 acid), cabbage-like (dimethyl sulfide) and fresh (acetaldehyde) on a linear scale from
259 0 (not perceivable) to 3 (strongly perceivable) in steps of 0.5 units. The attributes
260 were defined in a first session with the panelists as most relevant to describe the
261 overall aroma of orange juice. For the subsequent aroma profile analysis reference
262 solutions of the aroma compounds given in parentheses in 20 – 40-fold threshold
263 concentration (in water) were presented for each attribute. Samples (15 mL) were
264 presented in covered glass vessels (i.d. = 40 mm, total volume = 45 mL) at room
265 temperature, and the results obtained in two sessions were averaged and plotted in a
266 spider web diagram.

267 *Triangle Test.* In order to provide information on the differentiation of sensory
268 properties of samples, triangle tests were designed and interpreted according to the
269 method ISO 4120:2004.

270 *Determination of Odor Thresholds.* Odor thresholds were determined in tap water
271 as recently described.³⁹ Because of its pH dependent molecular properties, the or-
272 thonasal odor threshold of acetic acid was determined in an orange juice model ma-
273 trix, consisting of an aqueous solution of 4.5 % sucrose, 2% glucose, 2 % fructose,
274 1.1 % citric acid, 0.5 % ascorbic acid and 0.1 % sunflower oil (the pH was adjusted to
275 3.6).

276 *Odor Activity Values.* These were calculated as previously described.³⁸

277 **Results and Discussion**

278 **Aroma Profile of unstored NFC juice from Hamlin oranges.** First, the overall
279 aroma of the unstored juice was evaluated by an aroma profile analysis using 11
280 odor attributes agreed upon by the sensory panel in preliminary sessions. The evalu-
281 ation of the intensity of each attribute was trained using solutions of single odorants
282 representing the respective odors in a concentration by factors of approximately 50
283 above their odor threshold. The major odor attributes described in the unstored Ham-
284 lin orange juice were fresh with an intensity of 2.3 (Figure 1), followed by or-
285 ange/green (1.8), pungent (1.7), fruity (1.6) and green/grassy (1.5). The other six at-
286 tributes citrus/flowery, sour, caramel-like, clove-like, vanilla-like and cabbage-like
287 were ranked with a lower intensity.

288 **Identification of Aroma-Active Compounds in Hamlin orange juice.** To eluci-
289 date the compounds contributing to the overall aroma of the unstored Hamlin juice,
290 an aroma extract dilution analysis (AEDA) was carried out on the entire set of vola-
291 tiles isolated by extraction and SAFE distillation. A total of 51 aroma-active regions
292 could be located in the FD factor range of 8 to 8192 (Figure 2) among which two
293 compounds with a vanilla-like (**51**) and a coconut-like odor attribute (**45**) showed the
294 highest FD factors of 8192, followed by two compounds with a flowery (**26**) and a
295 smoky odor (**47**). Further compounds with a high FD factor were **3** (fir needle -like), **7**
296 (green), **10** (citrus-like), **21** (sour), **36** (deep-fried), **41** (metallic) and **42** (caramel-like).
297 A comparison of the retention indices, mass spectra and perceived odors (quality and
298 intensity) with the institute's database containing analytical and sensory data of ap-
299 proximately 1000 aroma compounds resulted in proposals for the chemical struc-
300 tures. These were confirmed by the analysis of reference compounds.

301 The results of the identification experiments in combination with the FD factors
302 showed that vanillin (**51**; Figure 3), 3a,4,5,7a-tetrahydro-3,6-dimethyl-2(3*H*)-

303 benzofuranone (winelactone) (**45**) followed by (R)-linalool (**26**) caused the respective
304 odors of the odor-active areas detected by AEDA (Figure 2). The enantiomeric purity
305 of linalool was higher than 95% (data not shown). Further odorants with high FD fac-
306 tors were α -pinene (**3**), hexanal (**7**), (R)-limonene (**10**), acetic acid (**21**), (*E,E*)-2,4-
307 decadienal (**35**), *trans*-epoxy-(*E*)-2-decenal (**40**) and 4-hydroxy-2,5-dimethyl-
308 3(*2H*)furanone (**41**). The results of the further identification experiments (Table 1)
309 showed that 45 out of the 51 odorants detected by GC/Olfactometry could be identi-
310 fied. In general, the results confirmed data of previous studies^{5,9,12,13,15,40-50} aimed at
311 identifying either volatile or odor-active compounds in orange juices of different ori-
312 gins and varieties. However, 2-ethyl-3- and 2-ethyl-5-methylpyrazine (**16**) and 3-
313 hydroxy-4,5-dimethyl-2(*5H*) furanone (**46**) are reported here as additional odorants in
314 orange juice, although both showed only low FD factors.

315 **Influence of a chilled storage** To elucidate changes occurring during chilled stor-
316 age of the Hamlin juice, its aroma profile was determined after 1, 2 and 10 months of
317 storage (Figure 4). A comparison with the profile of the unstored juice (black line in
318 Figure 4) indicated that in particular the freshness of the juice was decreased during
319 storage and also the pungent and green, grassy odor attributes were clearly lower in
320 the stored juices. This loss in odor intensity was already detectable after 1 month of
321 storage (dark green line in Figure 4).

322 To clarify the odorants responsible for these differences, the AEDA was applied on
323 a SAFE distillate obtained from the 10 months stored juice (10m; Table 2). A compar-
324 ison with the results obtained for the unstored juice (Ust; Table 2) revealed that the
325 majority of the 51 odorants was qualitatively identical in both samples. But, 4 com-
326 pounds were no longer detectable by GC/O in the stored juice, i.e., 1-penten-3-one
327 (**4**), (*Z*)-3-hexenal (**8**), (*E,Z*)-2,6-nonadienal (**28**) and 3-hydroxy-4,5-dimethyl-2(*5H*)
328 furanone (**46**). Because differences of two or one dilution step lie within the error

329 range of the AEDA, only the differences in FD factors determined for the following six
330 compounds may give additional hints, which odorant loss may contribute to the aro-
331 ma differences detected in the aroma profiles: hexanal (**7**), octanal (**14**), nonanal
332 (**18**), (*E,E*)-2,4-decadienal (**35**), 4-hydroxy-2,5-dimethyl-3(*2H*)-furanone (**41**) and van-
333 illin (**51**). On the other hand, the FD factor of only one compound, namely 2-methoxy-
334 4-vinylphenol (**44**) was higher in the stored juice compared to the unstored juice (Ta-
335 ble 2).

336 **Quantitative Analysis.** To get nearer to the reason for the aroma differences in
337 the juice, quantitative data were correlated with the odor thresholds of the odorants
338 by calculating odor activity values (ratio of concentration to odor threshold). Thus,
339 first a quantitative analysis of aroma compounds showing clear differences in their
340 FD factors as well as of compounds proposed in the previous literature as markers
341 for off-flavor in orange juices was performed mainly by means of stable isotope dilu-
342 tion assays.

343 In the unstored juice, (*R*)-limonene showed by far the highest concentration of
344 about 121 mg/kg; followed by acetaldehyde with 16.1 mg/kg, acetic acid with 5.5
345 mg/kg and myrcene with 1.5 mg/kg (Table 3). Moreover, α -pinene, linalool, hexanal,
346 ethyl butanoate, decanal, octanal and nonanal were found in concentrations between
347 99.6 and 757 $\mu\text{g}/\text{kg}$. 1-Penten-3-one, vanillin, (*Z*)-3-hexenal and 2-methoxy-4-
348 vinylphenol were measured in a lower concentration range between 0.74 and 35
349 $\mu\text{g}/\text{kg}$.

350 Compared to the unstored juice, already after one month the concentrations of ac-
351 etaldehyde and of (*Z*)-3-hexenal decreased significantly (Table 3), and 1-penten-3-
352 one was decomposed to about one tenth of its initial concentration. It should, howev-
353 er, be mentioned that (*Z*)-3-hexenal is not stable during a freezing/thawing pro-
354 cess.^{2,51} So, its initial concentration in the unstored juice was probably much higher.

355 Additionally, hexanal, nonanal and decanal decreased in their concentrations. On the
356 other hand, acetic acid and 2-methoxy-4-vinylphenol showed an increase already
357 after 1 month (Table 3). Monitoring the changes in concentrations of the 15 aroma
358 compounds after ten months indicated a continuous loss of (R)-limonene, myrcene,
359 α -pinene, (Z)-3-hexenal as well as of hexanal, octanal, nonanal and decanal. In par-
360 ticular, 1-penten-3-one and acetaldehyde fell below their detection threshold already
361 after two months of chilled storage. While e.g., (R)-linalool and ethyl butanoate were
362 quite stable, 3 compounds increased after ten months, namely acetic acid, 2-
363 methoxy-4-vinylphenol and vanillin (Table 3).

364 To confirm the trend in the different stabilities of the juice odorants, the storage tri-
365 al was repeated using NFC juice from Hamlin oranges of the following harvest year.
366 In this trial, further 6 compounds were added to the set of 15 aroma compounds ana-
367 lyzed in the first year: ethyl hexanoate, (E,E)-2,4-decadienal, β -ionone, α -terpineol
368 and carvone. The latter two odorants have previously been suggested as off-flavor
369 compounds in orange juice.^{7,9,14} The same trends in the stability of the odorants were
370 observed (Table 4). Besides ethyl butanoate, also further two esters, (S)-ethyl 2-
371 methylbutanoate and ethyl hexanoate, were quite stable during storage for six
372 months, and the same was true for (R)-linalool. However, 1-penten-3-one and acet-
373 aldehyde rapidly disappeared during storage as already observed for the juice from
374 the year before. In addition, (Z)-3-hexenal and (E,E) 2,4-decadienal as well as all
375 saturated aldehydes were clearly reduced during storage. But, the previously sug-
376 gested off-flavor compounds in orange juice, carvone and vanillin, did not show an
377 increase compared to the unstored juice. But, the concentration of α -terpineol in-
378 creased from 183 $\mu\text{g}/\text{kg}$ to nearly the ten-fold amount of 1100 $\mu\text{g}/\text{kg}$.

379 As a next step, a calculation of odor activity values was done on the unstored
380 Hamlin juice as well as on the five stored samples (Table 4 and Table 5). In the un-

381 stored juice, (R)-limonene, (R)-linalool, myrcene and acetaldehyde followed by ethyl
382 butanoate showed the highest odor activity values. Neither α -terpineol, carvone and
383 vanillin nor 2-methoxy-4-vinylphenol were present above their odor threshold, while
384 acetic acid was already present with an OAV of 8.9 already in the unstored juice. A
385 comparison of the OAVs in the unstored juice and the 6 months stored juice clearly
386 indicated that in particular 1-penten-3-one and acetaldehyde fell below their odor
387 threshold after 6 months and, are, thus, lost as contributors to the overall aroma pro-
388 file. A reduced effect in the aroma contribution indicated by lower OAVs also oc-
389 curred for hexanal, octanal, nonanal, decanal, (Z)-3-hexanal and (E,E)-2,4-
390 decadienal.

391 **Aroma-Active Compounds in NFC Valencia Orange Juice.**

392 To indicate whether similar aroma losses also occur in juices from other varieties,
393 the same series of experiments was done on NFC juice from Valencia oranges. The
394 study started with the aroma profile analysis of the unstored juice and a juice stored
395 for 10 months (Figure 5). The most distinct aroma impression in the unstored juice
396 was orange/green" (2.0) and "fresh" (1.7), followed by the attributes "pungent" (1.4),
397 "fruity" (1.5) and "citrus/flowery" (1.4). The qualities "green/grassy" (1.3), "sour" (1.1)
398 and "caramel-like" (1.0) were rated less intense, while the odor impressions "clove-
399 like" (0.7), "vanilla-like" (0.5) and "cabbage-like" (0.2) showed a low impact on the
400 overall aroma of this juice. In the 10 months stored juice, the most obvious loss of
401 intensity was detected for the odor quality orange/green. The changes were similar
402 compared to those observed for the Hamlin juice (Figure 4).

403 An aroma extract dilution analysis applied on the unstored NFC juice from Valen-
404 cia oranges followed by identification experiments revealed the same odor-active
405 compounds in the Valencia NFC juice as in the Hamlin juice, although the FD factors
406 were different (see supplementary information) pointing to differences in the amounts

407 of several odorants between both unstored juices. Furthermore, an AEDA applied on
408 the stored Valencia juice also resulted in changes for the same aroma compounds
409 (data not shown). Therefore, the same set of aroma compounds as analyzed in the
410 Hamlin juices was also quantitated in the unstored and the stored Valencia juice (Ta-
411 ble 6). In the unstored juice, (R)-limonene, acetic acid and acetaldehyde followed by
412 linalool and myrcene showed the highest concentrations. Compared to the unstored
413 juice from the Hamlin oranges, in particular the concentrations of (R)-limonene, linal-
414 ool as well as octanal, nonanal and decanal showed higher concentrations in the Va-
415 lencia juice (compare data in Tables 4 and 6). These differences might be the reason
416 for a more intense orange-like/green note in the overall aroma profile of the Valencia
417 juice (Figure 1 and Figure 5).

418 When the stability of the compounds during chilled storage was monitored, the
419 same trends as for Hamlin orange juice were observed (Table 6). For example, 1-
420 penten-3-one and acetaldehyde showed a very rapid decrease and all unsaturated
421 and saturated aldehydes were significantly degraded during storage. On the other
422 hand, (R)-linalool and all esters were stable, and besides vanillin, in particular acetic
423 acid, α -terpineol as well as 2-methoxy-4-vinylphenol increased in concentration. The
424 calculation of odor activity values revealed (R)-linalool followed by (R)-limonene and
425 myrcene with the highest odor activities followed by acetaldehyde and ethyl buta-
426 noate in the unstored NFC juice (Table 7). Except acetaldehyde, which was below its
427 odor threshold in the 10 months stored juice, the other 4 compounds still showed the
428 highest odor activity after a 10 months storage. However, significant losses in odor
429 activity were measured for (*E,E*)-2,4-decadienal, hexanal, octanal, nonanal and de-
430 canal. But, also in the NFC Valencia juice neither 2-methoxy-4-vinylphenol, vanillin
431 and α -terpineol nor carvone were found as contributors to the changes in the overall
432 aroma, i.e. as off-flavor compounds. By application of the same concept on a Valen-

433 cia NFC juice from a second harvest year nearly identical results were obtained (data
434 not shown).

435

436 **Sensory experiments on odorant contribution**

437 During storage of the Hamlin juice, exclusively a degradation of odorants was de-
438 tected, but no significant increase in any odor active compound was observed. Thus,
439 spiking a stored juice with the lost amounts of the odorants should bring back the
440 aroma profile of the unstored juice. Thus, the following sensory experiments were
441 carried out to study this assumption (Figure 6). In a six months stored juice the con-
442 centrations of 12 aroma compounds were made up to their initial concentrations de-
443 termined in the unstored juice (Table 8). While the six months stored juice and the
444 unstored juice were clearly distinguishable by their overall aroma profiles (data not
445 shown), the spiked juice could not be distinguished from the unstored juice (Table 8)
446 ($\alpha = 0.2$). In a second set of experiments, aroma compounds were grouped according
447 to three aroma impressions, namely “green”, “fresh/ pungent”, and “citrus/ orange-
448 like” and subgroups correlating with this odor attribute were separately administered
449 to the six months stored juice. The stored juice spiked with the two “green” com-
450 pounds (Z)-3-hexenal and hexanal was clearly differentiated ($\alpha = 0.01$) (Table 8) from
451 the unstored juice. However, after administering only the “fresh, pungent” compounds
452 1-penten-3-one and acetaldehyde, the panel could not differentiate between the
453 spiked and the unstored sample ($\alpha = 0.2$). In addition, also spiking 4 aldehydes,
454 namely octanal, nonanal, decanal and (E,E)-2,4-decadienal showed a positive effect
455 on the aroma of the stored juice. Also this partial recombine could no longer be dis-
456 tinguished from the unstored juice ($\alpha = 0.2$). These results corroborate the importance
457 of 1-penten-3-one as well as acetaldehyde, octanal, nonanal, decanal and (E,E)-2,4-
458 decadienal for the overall aroma of orange juice.

459 With respect to fresh orange juice, these results confirm data of previous investiga-
460 tions from our working group on fresh orange juices^{2,5,6,15} suggesting that besides
461 esters, such as ethyl butanoate, and terpenoids like (R)-limonene, several com-
462 pounds known as degradation products of lipid hydroperoxides, such as 1-octen-3-
463 one, (Z)-3-hexenal and (E,E)-2,4-decadienal and saturated aldehydes are important
464 contributors to the aroma of unstored (fresh) orange juices. In addition, 1-penten-3-
465 one and acetaldehyde were established as an important key odorant in NFC orange
466 juices. The formation of 1-penten-3-one can be assumed from the 15-hydroperoxide
467 of linolenic acid by a radical mechanism (Figure 7) which is similar to a mechanism
468 proposed for the formation of 1-octen-3-one from linoleic acid in mushrooms.⁵² How-
469 ever, in particular the oxidation of the intermediate alcohol to the ketone has not yet
470 been proven in both cases. Thus, it might be assumed that 1-penten-3-one is enzy-
471 matically formed in the orange fruit.

472 Furthermore, while previous investigations^{15,16} focused on the storage of juice
473 made from concentrate at room temperature or even under forced conditions, these
474 investigations focused for the first time on changes of the aroma compounds of NFC
475 orange juice during chilled storage, which is common in the juice industry. Our results
476 clearly show that despite these gentle storage conditions, changes in the overall
477 aroma profiles of juices from two orange varieties occurred leading to a decrease in
478 the intensity of several aroma attributes compared to the unstored juice. However, an
479 important role of previously suggested off-flavor compounds in orange juice, such as
480 carvone, 2-methoxy-4-vinylphenol or vanillin for changes in the overall juice aroma
481 could be ruled out for such chilled stored juices.

482 But, as confirmed by sensory experiments, the rapid decomposition of 1-penten-3-
483 one and acetaldehyde are particularly involved in the loss of the typical aroma of the
484 unstored juice. In addition, the continuous degradation of (Z)-3-hexenal, hexenal, oc-

485 tanal, nonanal, decanal, and (*E,E*)-2,4-decadienal for sure contribute to the overall
486 changes in juice aroma. However, neither the pathways for the decomposition of the
487 1-penten-3-one nor for the losses of the aldehydes are yet known. This challenge will
488 be addressed in further investigations.

^{a)} Odor threshold concentrations in water if not stated otherwise. ^{b)} Odor activity values were calculated by dividing the concentrations in table 4 by the odor threshold concentrations; n.c.: not calculated. ^{c)} The threshold concentration of acetic acid was determined in an orange juice matrix at a pH value of 3.6. ^{d)} Threshold concentration in water according to ²³. ^{e)} Threshold concentration of the (S)-isomer in water.

Table 6. Changes in the concentrations of 21 odor-active compounds in Valencia NFC orange juice (harvest year 2) during storage.

Odorant	Concn. ^{a)} [$\mu\text{g}/\text{kg}$] after			
	0	1	6	10 months
(<i>R</i>)-limonene	188000	175000	153000	124000
acetic acid	12700	20900	21700	23700
acetaldehyde	16100	11900	n.d.	n.m.
(<i>R</i>)-linalool	1710	1560	1630	1560
myrcene	1620	1550	1380	1150
α -pinene	800	630 ^{b)}	458	337
octanal	790	650	384	377
decanal	651	520	253	225
α -terpineol	412	808	1870	2740
ethyl butanoate	374	373	371	372
hexanal	277	192	140	93.3
nonanal	160	141	96.6	84.3
carvone	105	105	107	106
ethyl hexanoate	80.5	67.2	56.6	49.5
vanillin	44.0	51.8	58.9	63.5
1-penten-3-one	30.2	1.5	n.d.	n.m.
2,3-butanedione	21.1	20.1	21.5	21.1
β -ionone	10.3	10.4	9.8	10.0
(<i>E,E</i>)-2,4-decadienal	8.3	3.1	0.5	0.3
(<i>S</i>)-ethyl 2-methylbutanoate	3.2	3.3	3.6	3.7
(<i>Z</i>)-3-hexenal	1.6	0.4	0.1	0.1
2-methoxy-4-vinylphenol	1.5	2.3	3.2	6.0

^{a)} Data are mean values of triplicates; standard deviation $\geq 10\%$; n.m.: not measured; n.d.: not detected.

Table 7. Changes in odor activity values (OAV) of 21 aroma compounds in NFC juice from Valencia oranges (harvest year 2) during storage

Odorant	Threshold ^{a)} [µg/kg]	OAV ^{b)} after storage for			
		0	1	6	10 months
(<i>R</i>)-linalool	0.087	20000	18000	19000	18000
