An approach to the C(7)–C(15) fragment of galbonolide B 2 has been completed in which the diene fragment 51 was assembled from (R)-3-*tert*-butyldimethylsilyloxypentan-2-one 29 by conversion into the unsaturated ester 30, acylation of the sulfone 47 using this ester, reductive desulfurisation, methylenation using a Wittig reaction and deprotection. Following model studies, the aldehyde 62, prepared by oxidation of the alcohol 51, was converted into a mixture of the epimeric alcohols 63 and these were converted into the di(methylene)tridecadienoic acid 65 using a phosphine catalysed Ireland–Claisen rearrangement. Sharpless epoxidations of the alcohol 67 using either L-(+)- or D-(-)-diethyl tartrate were highly stereoselective and gave the epoxides 68 and 69 which were clearly distinguishable. Model studies using the heptadiene monoepoxide 70 led to a synthesis of the monoprotected dihydroxy aldehyde 76 so establishing a protocol for the introduction into the vicinal diol of the galbonolides. Finally, aldol addition of *tert*-butyl acetate to the aldehyde 78 followed by selective protection, deprotection and cyclisation completed a synthesis of the macrolide 85.

assigned to galbonolide B by reference to the Celmer model¹ was subsequently revised to the (4S,13S)-diastereoisomer 2 on the basis of an X-ray structure determination and a total synthesis in which a key step was the stereoselective alkylation of an enolate anion derived from dioxolane 3 using the iodide 4.² In addition an ingenious stereoselective synthesis of the C(7)–C(15) fragment 6 has been described based on the Ireland–Claisen rearrangement of the propanoate 5 followed by 1,4-elimination to introduce the conjugated diene.³ We here report an approach to the C(7)–C(15) fragment and studies into strategies for completion of a synthesis of galbonolide B 2. This work was carried out before the structure of the natural product was revised and was directed towards the synthesis of

the (4R, 13R)-diastereoisomer **1**. Nevertheless, the chemistry should be applicable for a synthesis of the natural product.

At the onset of our work, it was intended to prepare the α , β -unsaturated ketone **8** by means of a Wittig condensation between the keto ylid **9** and the 3-alkoxypentan-2-one **10**, and to convert the ketone into the diene **7**, corresponding to the C(7)–C(15) fragment of galbonolide B, by methylenation (Scheme 1).

Results and discussion

The diene 18 was synthesized to gain familiarity with the proposed chemistry, see Scheme 2. The racemic 3-alkoxypentan-2one 14 was prepared in three steps from 2-methyl-1,3-dithiane 11, with better results for the lithiation of the dithiane being obtained using *sec*-butyllithium. Although condensations of the ketone 14 with either the keto phosphorane 19 or the keto phosphonate 20 were unsuccessful (the reactants were generally recovered unchanged), the ketone 14 reacted cleanly with triethyl phosphonoacetate to give the unsaturated ester 15 as a 10:1 mixture of (*E*)- and (*Z*)-isomers (NOE). Ester 15 was converted into the Weinreb amide 16 which gave the ketone 17 on treatment with butyllithium, and a Wittig reaction of this enone with methylene(triphenyl)phosphorane gave the

conjugated diene 18. The difficulties in reacting the keto phosphorane 19 or keto phosphonate 20 with the ketone 14 have precedent⁴ and may be due, at least in part, to the steric hindrance to attack on the 2-substituted ketone. However, the preparation of the ester 15 using triethyl phosphonoacetate, followed by conversion of the ester functionality into the ketone by addition of the organometallic reagent, provided a useful alternative synthesis of the α , β -unsaturated ketone. It was now necessary to prepare the enantiomerically enriched ester 15 for reaction with a chiral organometallic reagent to achieve a synthesis of the target fragment 7.

Commercially available isobutyl (*R*)-lactate **21** was converted into its benzyloxymethyl ester **22**⁵ which was reduced to (2*R*)-2-(benzyloxymethoxy)propanal **23** (Scheme 3). Chelation controlled addition⁶ of ethylmagnesium bromide to **23** was enhanced by the presence of zinc bromide⁷ and gave predominantly the *syn*-alcohol **24** with *syn*: *anti*-stereoselectivities within the range *syn*: *anti* = 97:3 to 94:6, better stereoselectivity being obtained for smaller scale reactions. The configuration of the *syn*-alcohol **24** at C(3) was checked by comparison of the ¹H NMR chemical shifts of its *O*-acetylmandelates **25** and **26**.⁸

Protection–deprotection and oxidation then gave the 3-silyloxyketone **29** which was condensed with triethyl phosphonoacetate to give the (*R*)-ester **30**. The optical purity of this ester was checked by desilylation and conversion of the hydroxy ester **31** into its (*R*)- and (*S*)-Mosher's derivatives **32** and **33**. Comparison of the ¹⁹F NMR spectra of these indicated that the optical purity of the hydroxy ester **31** was in the region of 84–96%, with better enantiomeric excesses being obtained for smaller scale preparations.

The bromide **37** was prepared from methyl (R)-3-hydroxy-2methylpropanoate **34**, see Scheme 4, but preliminary attempts to convert this into either an organolithium or Grignard reagent for reaction with the Weinreb amide derived from the ester **30** resulted only in decomposition. The bromide was therefore converted, *via* sulfide **38**, into the sulfone **39** and conditions developed for the acylation of the lithiated sulfone by the ester **30** to yield ketone **40**. Significant improvements in the yield of this acylation were obtained when a solution of magnesium bromide–diethyl ether was added to the lithiated sulfone prior

to the addition of the ester.⁹ Reductive desulfurisation ¹⁰ then gave the ketone **41** which was converted into the diene **42** using a Wittig reaction. It remained to deprotect the primary alcohol of **42** to complete a synthesis of the C(7)–C(15) fragment of the galbonolides. However, attempts to remove the *p*-methoxybenzyl group oxidatively using dichlorodicyanoquinone¹¹ or ceric ammonium nitrate¹² resulted in decomposition, and the use of other procedures¹³ for removal of the *p*-methoxybenzyl group resulted in either decomposition, perhaps because of instability of the alcohol (*vide infra*) or recovery of starting material.

It was necessary to investigate the use of other protecting groups for the primary alcohol. Attempted deprotection of the SEM-ether 43,¹⁴ prepared following the route used to prepare the *p*-methoxybenzyl ether 42, gave rise to a complex mixture of products even when buffered conditions were used. However,

monodesilylation¹⁵ of the bis-*tert*-butyldimethylsilyl ether **50**, prepared as outlined in Scheme 5, gave the required primary

alcohol **51** in excellent yield (87%). This alcohol was found to be very sensitive to acid with cyclisation to the epimeric tetra-hydrofurans **52** being observed on standing in chloroform.

This phase of the work completed a convergent synthesis of the alcohol **51** which corresponds to the C(7)–C(15) fragment 7 of the galbonolides. At this point, the recently reported phosphine catalysed Ireland–Claisen rearrangement of α , β -unsaturated esters¹⁶ was identified as a useful procedure for the preparation of advanced intermediates for a synthesis of galbonolide B **2**. To gain familiarity with this chemistry, model studies were carried out starting with (racemic) 2-phenyl-propanal **53**.

Addition of prop-2-enyllithium to 2-phenylpropanal **53** gave a mixture of the secondary alcohols **54**¹⁷ which were acylated with acryloyl chloride to give the esters **55** (Scheme 6). Rearrangement of these was achieved by heating a solution with tricyclohexylphosphine, trimethylsilyl chloride and 1,8diazabicyclo[5.4.0]undec-7-ene (DBU) in acetonitrile at 75 °C for 17 h, and gave a good yield of the dienyl acid **57** *via* the *in situ* generation and rearrangement of the silylated conjugate addition product **56**.¹⁶ The use of trimethylsilyl chloride rather than triethylsilyl chloride was preferred because of the faster hydrolysis of the trimethylsilyl ester **58** compared with its triethylsilyl analogue **59**. Esterification of the acid **57** using diazomethane gave the methyl ester **60** which was reduced using diisobutylaluminium hydride to give the alcohol **61**.

The same procedures were used to convert the aldehyde **62**, prepared by oxidation of alcohol **51**, into the chain extended allylic alcohol **67**, see Scheme 7. Thus treatment of the aldehyde with 2-lithiopropene, generated in this case from 2-bromopropene by halogen-metal exchange using *tert*-butyllithium, gave the epimeric alcohols **63**. Alternatively, on a small

Two problems have to be addressed for a conversion of either the ester **66** or alcohol **67** into galbonolide B; the stereoselective introduction of the vicinal diol unit, and the chain extension to compete the assembly of the carbon framework. Moreover the sensitivity of the natural product to both acid and base¹ will determine the conditions allowable for any final deprotection.

It was considered that stereoselective epoxidation–epoxideopening could be used for the introduction of the vicinal diol moiety and this approach was shown to be feasible by Sharpless epoxidation of the allylic alcohol **67**.¹⁹ The use of L-(+)- and D-(-)-diethyl tartrate gave rise to the (*S*)- and (*R*)-epoxides **68** and **69** which were distinguishable by ¹H NMR spectroscopy.

Excellent stereoselectivities were observed in these epoxidations with only traces of the minor diastereoisomer being obtained in each case. As preliminary studies into the ring-opening of these epoxides using oxygen nucleophiles were not successful, model studies were carried out at this juncture using the epoxides 70 prepared from the allylic alcohol 61, see Scheme 8. As the starting alcohol was racemic, these epoxides were obtained as a 1:1 mixture of epimers at C(6), which could not be separated, but this mixture was used since it was felt that the remote chiral centre would have little effect on the chemistry of the epoxide.

The epoxides 70 were converted into the carbamate 71²⁰ and the carbonate 72.21 The Lewis acid induced ring-opening reactions of these were then studied as a route to the dioxolanone 73. The choice of solvent was found to be important in these reactions. Aluminium trichloride, boron trifluoride-diethyl ether and diethylaluminum chloride all gave the dioxolanone 73 in yields of 40-45% from the benzyl carbonate 72 if ether was used as the solvent, a similar yield being obtained from the carbamate 71 using perchloric acid in acetonitrile. However better yields were obtained in dichloromethane, for example a 76% yield of the dioxolanone 73 was obtained from the benzyl carbonate 72 using aluminium chloride in this solvent and 69% was obtained using boron trifluoride-diethyl ether. The structure of the dioxolanone 73 was assigned on the basis of its spectroscopic data with the configuration at the tertiary centre being assigned by analogy with literature reactions.^{20,21} Protection of the hydroxymethyldioxolanone gave the (2-trimethylsilylethoxy)methyl ether 74 which was hydrolysed to the diol 75. This in turn was oxidized to the aldehyde 76 which structurally corresponds to the vicinal diol containing the C(3)-C(8)fragment of galbonolide B.

At this stage, it was decided to investigate procedures for the addition of the three remaining carbons to complete the synthesis of the carbon skeleton of galbonolide B. Preliminary attempts to effect stereoselective addol reactions of the aldehydes 76 or 77, prepared by oxidation of the hydroxy epoxide 70, using enol borinates gave rise to complex mixtures of products. However, oxidation of the alcohol 67 using tetrapropyl-

ammonium perruthenate $(TPAP)^{22}$ gave the aldehyde **78** and addition of the lithium enolate generated from *tert*-butyl acetate using lithium hexamethyldisilazide gave the aldol adducts **79** as a mixture of epimers at C(3) (Scheme 9). These were protected as their *tert*-butyldiphenylsilyl ethers **80** as it was expected that removal of the *tert*-butyldimethylsilyl ether from C(13) would be faster than removal of the *tert*-butyldiphenylsilyl ether from C(3) so providing access to cyclisation precursors. However, this was not found to be the case. After cleavage of the *tert*-butyl ester, deprotection of the hydroxy group at C(3) by cleavage of the *tert*-butyldiphenylsilyl ether was faster than deprotection at C(13). Indeed deprotection of the *tert*-butyldimethylsilyl ether from C(13) required prolonged treatment with an excess of tetrabutylammonium fluoride.

Other protecting groups were screened for protection of the C(3)-hydroxy group. The alcohol **79** was converted into its (2-trimethylsilylethoxy)methyl ether **81**, but subsequent cleavage of the *tert*-butyl ester using trimethylsilyl triflate and triethylamine to obtain the free acid, was accompanied by elimination of the 3-substituent and gave the α , β -unsaturated acid **86** (68%) as the major product. However, after protection of the 3-hydroxy group as its *p*-methoxyphenoxymethyl ether **82**,²³ cleavage of the *tert*-butyl ester gave some of the required bisprotected dihydroxy acid **83** (35%), although the elimination product **86** was still obtained as a significant by-product (30%). Selective mono-deprotection of the *tert*-butyldimethylsilyl ether **83** by treatment with tetrabutylammonium fluoride then gave the hydroxy acid **84** which was cyclised to the macrolide **85** using the modified Yamaguchi method²⁴ in a yield of 43%.

Conclusions

The work outlined in this paper provides a basis for a proposed synthesis of galbonolide B. Aspects of general interest include the development of the highly stereoselective chelation controlled addition of ethylmagnesium bromide to the aldehyde 23, the completion of the convergent synthesis of the diene 51, the use of the phosphine promoted Ireland-Claisen rearrangement for the efficient synthesis of the tetraene 67, the development of the ring-opening of the hydroxy epoxide 70 leading to the mono-protected dihydroxy aldehyde 76, and the completion of the synthesis of the macrocyclic analogue 85 of galbonolide B. The convergent synthesis of the C(7)–C(15) fragment 51 makes this intermediate available in significant quantities. The phosphine induced Ireland-Claisen rearrangement provides a swift access to the tetraene 67 and modification of the epoxide 68 following the chemistry used in the synthesis should give access to the fully functionalised C(3)-C(15) part of galbonolide B including the vicinal diol containing component. Conditions have been found for the final stages of a synthesis including assembly of the macrocyclic ring. Further work in this area would concentrate on improvements to the protecting group strategy and completion of the synthesis.

C₂₈H₄₄NO₆ requires *M*, 490.3169); *v*_{max}/cm⁻¹ 3406, 1714, 1508, 1215, 1085 and 1004; $\delta_{\rm H}$ 0.94 (6 H, m, 8-CH₃, 15-H₃), 1.56 (3 H, s, 6-CH₃), 1.64 (2 H, m, 14-H₂), 1.78 (3 H, s, 12-CH₃), 2.10 (2 H, d, J 7, 9-H₂), 2.59 (3 H, m, 2-H₂, 8-H), 2.71 (2 H, s, 5-H₂), 3.79 (3 H, s, OCH₃), 4.00 (1 H, t, J 6.5, 13-H), 4.65 (1 H, m, 3-H), 4.90 (1 H, s, 10-CH), 5.04 (3 H, m, 4-CH, 7-H, 10-CH'), 5.11 and 5.19 (each 1 H, d, J7, OCHHO), 5.22 (1 H, s, 4-CH'), 5.83 (1 H, s, 11-H) and 6.83 and 6.98 (each 2 H, d, J 9, ArH); $\delta_{\rm C}$ 10.1, 13.1, 15.8, 20.6, 27.8, 31.5, 39.7, 42.2, 55.6, 77.2, 79.5, 91.6, 114.5, 115.1, 115.2, 117.2, 127.2, 130.2, 134.6, 139.3, 143.9, 151.5 and 154.6; m/z (C.I.) 490 (M⁺ + 18, 0.2%), 472 (M⁺, 0.2), 455 (3), 349 (2) and 124 (100).

2,6-Dichlorobenzoyl chloride (0.016 cm³, 0.111 mmol) was added to triethylamine (0.017 cm³, 0.122 mmol) and the hydroxy acid 84 (25 mg, 53 µmol) in tetrahydrofuran (0.5 cm³). The mixture was stirred for 2 h, filtered, diluted with toluene (25 cm³) and added slowly, over 2 h, to 4-(dimethylamino)pyridine (65 mg, 0.53 mmol) in toluene (10.6 cm³) at 95 °C. When the addition was complete, the mixture was stirred for 0.5 h, cooled and concentrated under reduced pressure. The residue was dissolved in ether, washed with aqueous hydrogen chloride (1 M), saturated aqueous sodium hydrogen carbonate, brine and dried (MgSO₄). Concentration under reduced pressure and flash chromatography of the residue [light petroleum:ether (10:1)] gave the title compound 85 (10.5 mg, 43%), as mixtures of epimers at C(3) (Found: M^+ + H, 455.2803. $C_{28}H_{39}O_5$ requires M, 455.2797); $v_{\text{max}}/\text{cm}^{-1}$ 1734, 1647, 1622, 1508, 1442, 1243, 1214, 1079, 1015, 903 and 828; $\delta_{\rm H}$ 0.84 and 0.85 (1.2 H and 1.8 H, t, J 7.5, 2'-H₃), 0.96 and 1.01 (1.2 H and 1.8 H, d, J 7, 8-CH₃), 1.40 (1.2 H, s, 6-CH₃), 1.63-1.76 (5.6 H, m, 6-CH₃, 12-CH₃, 1'-H₂), 1.81 (1.2 H, s, 12-CH₃), 2.03-2.30 (2 H, m, 9-H₂), 2.38 (0.4 H, m, 8-H), 2.53-2.92 (4.6 H, m, 2-H₂, 5-H₂, 8-H), 3.80 and 3.81 (1.8 H and 1.2 H, s, OCH₃), 4.63 (1 H, t, J 7, 13-H), 4.77 (1 H, m, 3-H), 4.84–5.32 (7 H, m, OCH₂O, 4-CH₂, 7-H, 10-CH₂), 5.86 and 5.88 (0.4 H and 0.6 H, s, 11-H) and 6.81–7.07 (4 H, m, ArH); δ_c 8.6, 9.1, 14.7, 15.8, 16.0, 16.5, 20.3, 22.9, 25.2, 25.9, 33.1, 34.6, 39.9, 40.8, 42.0, 45.1, 45.2, 46.2, 55.7, 73.3, 76.8, 77.2, 78.1, 79.9, 91.57, 91.64, 113.8, 114.3, 114.4, 114.6, 115.1, 116.5, 117.1, 117.2, 126.4, 129.7, 130.5, 130.8, 133.2, 133.7, 134.1, 134.4, 143.0, 144.2, 145.1, 151.4, 151.5, 154.5, 154.6, 169.5 and 170.1; m/z (C.I.) 472 (M⁺ + 18, 18%), 455 (M⁺ +1, 10), 331 (63), 155 (45) and 124 (100).
