Received January 20, 2000

Alkynylgold(I) complexes have been prepared from the angular bis(alkyne) MeC_6H_3 -3,5-(CCH)₂, in which the alkyne units are rigidly fixed at an angle of 120° to each other. Reaction with $[AuCl(SMe_2)]$ and base yields the shock-sensitive, insoluble compound $[{MeC_6H_3-3,5-}]$ $(CCAu)_{2}$ (2), which reacts with isocyanide, phosphine, or phosphite ligands (L) to give $[MeC_6H_3-3,5-(CCAuL)_2]$ (3; L = P(OPh)₃, P(OMe)₃, PPh₃, PMePh₂, t-BuNC, MeNC). The complexes with $L = P(OMe)_3$, PMePh₂ exist in the solid state as infinite one-dimensional ribbon structures in which neighboring molecules are associated through secondary goldgold bonding. Complexes with diisocyanide ligands $1,4-C_6R_4(NC)_2$ (R = H, Me) have the formula $[{MeC_6H_3-3,5-(CCAu)_2(\mu-LL)}_n]$ and are insoluble in organic solvents; they are suggested to have a zigzag polymeric structure. In contrast, complexes with diphosphine ligands $(CH_2)_n(PPh_2)_2$ (n = 1-6) are soluble and are suggested to be the cyclic tetragold(I) complexes of formula [$\{MeC_6H_3-3,5-(CCAu)_2(\mu-LL)\}_2$]; the ring size varies from 24 to 34, depending on n.

Introduction

There has been much interest in the use of pdiethynylarenes as reagents in forming rigid-rod, organometallic polymers, which may contain square-planar (Ni(II), Pd(II), Pt(II)) or octahedral (Rh(III), Fe(II), Ru-(II), Os(II)) metal centers.^{1,2} These compounds have interesting nonlinear optical properties, which might lead to materials applications.¹⁻³ A number of gold(I) polymers, with linear gold(I) centers, have been prepared, and their emission spectra suggest that there is indeed some conjugation present, though the polymers are insoluble.^{4,5} Neutral polymers require one alkynylgold group and one other neutral ligand, and examples of known oligomeric or polymeric structures are illustrated in Chart 1. If the dialkyne or supporting ligand is flexible, then rings and even catenated rings rather than polymers may be formed (Chart 1).5-7

angle between the ethynyl groups is 120°, rather than the more common 180° in rigid-rod ligands. There is limited related work, including a binuclear cationic complex containing octahedral iridium(III) centers bridged by 1,2-diethynylbenzene.⁸ Also, 1,3,5-triethynylbenzene has been exploited in forming complexes with platinum, iridium, and gold that may have novel 2-D polymeric structures.^{5,9–11}

Results and Discussion

Synthesis of the Bis(alkyne) and Model Gold(I) Complexes. The ligand 3,5-diethynyltoluene was prepared by reaction of the protected alkyne (trimethylsilyl)acetylene with 3,5-dibromotoluene, followed by removal of the trimethylsilyl protecting groups with potassium hydroxide (Scheme 1). A similar route has been used to prepare 3,5-diethynylpyridine.¹²

3,5-Diethynyltoluene (1) was converted to the polymeric digold(I) diacetylide derivative [{MeC₆H₃-3,5-(C \equiv CAu)₂}_n] (2) by reaction with [AuCl(SMe₂)] in the presence of sodium acetate (Scheme 1). Complex 2 was isolated as a bright yellow, insoluble powder, and like other gold(I) acetylides, it is presumed to have a polymeric structure in which each acetylide is σ -bonded (η^1) to one gold atom and π -bonded (η^2) to another.¹³ Some evidence for such a structure is obtained from the IR spectrum of 2, which exhibits a weak band at 1985 cm⁻¹; this band is 132 cm⁻¹ lower than in the precursor 1 and indicates that the alkynyl groups are acting as π -donors, but the insolubility of 2 did not allow characterization by solution NMR.

Figure 1. View of the structure of complex **3b**, showing a molecule and its two neighbors connected by Au…Au bonds (25% probability ellipsoids are shown).

Figure 2. View of the structure of complex **3d**, showing parallel ribbons formed by the two independent molecules (25% probability ellipsoids are shown).

Complex **2** was converted to more soluble complexes $[MeC_6H_3-3,5-(C\equiv CAuL)_2]$ (**3**) by reaction with monodentate isocyanide or phosphorus-donor ligands as shown in Scheme 1. The pale yellow phosphite, phosphine, and isocyanide complexes were readily characterized by their spectroscopic properties. The IR spectra for these compounds exhibit weak bands near 2120 cm⁻¹ due to $\nu(C\equiv C)$ and, for the isocyanide complexes, strong bands at 2230–2260 cm⁻¹ due to $\nu(N\equiv C)$.¹⁴ The ¹H NMR spectra of **3** contain the expected resonances due to both the alkynyl and neutral ligands, while the phosphine and phosphite complexes each give a single resonance in the ³¹P NMR spectra. Details are listed in the Experimental Section. Only **3f** was insufficiently soluble to give a satisfactory NMR spectrum.

Two of the model complexes, **3b** and **3d**, have been characterized crystallographically, and their structures are shown in Figures 1 and 2, while selected bond lengths and angles are presented in Tables 1 and 2.

Molecules of **3b** (L = P(OMe)₃; Figure 1) have the expected structure with roughly linear C–C≡C–Au–P units held at 120° to each other.^{4–6,11,15} The intramolecular distances between the two gold and phosphorus atoms (Au(1)–Au(2) = 10.44 Å, P(1)–P(2) = 14.27 Å) are long, such that common bidentate ligands clearly could not span the two gold(I) centers intramolecularly. In the solid state, the molecules are associated to give a ribbon structure, as shown in Figure 1, by formation

of intermolecular Au…Au bonds (Au(1)-Au(2#) (e.g., Au(1A)-Au(2B) in Figure 1, which shows three equivalent molecules designated A-C = 3.2196(9) Å).

The unit cell for **3d** ($L = PMePh_2$, Figure 2) contains two independent but similar molecules. The molecular structure is similar to that of **3b**. Each independent molecule, containing Au(1), Au(2) and Au(3), Au(4), respectively, forms its own independent but parallel ribbon structure as shown in Figure 2. The gold ... gold distances, which define the intermolecular aurophilic attraction, are slightly shorter $(Au(1)\cdots Au(2\#) = 3.124$ -(2) Å; Au(3)···Au(4#) = 3.146(2) Å) than in **3b** (3.2196-(9) Å).

Synthesis of Ring and Zigzag Polymeric Complexes. Linear, one-dimensional polymers [(Au-C=C- $Ar-C \equiv C-Au-L-L$)_{*x*} (Ar = linear arene spacer group, L-L = p-diisocyanoarenes or diphosphines) have been prepared by reaction of linear digold(I) diacetylide complexes, $[(Au-C \equiv C-Ar-C \equiv C-Au)]_x$, with the corresponding bidentate ligand L-L.⁴ However, a better procedure when both precursor and product are insoluble is to convert the insoluble gold(I) acetylide to a soluble complex by reaction with *t*-BuNC and then replace the *t*-BuNC with the bidentate ligand. This method was used to prepare the insoluble diisocyanobenzene derivatives 4a,b shown in Scheme 2.

The products 4a,b were formed as yellow solids that

were insoluble in common organic solvents. The polymeric compounds have a ν (N=C) value of 2205 cm⁻¹ which is similar to the $\nu(N=C)$ values of the model compounds.¹⁴ In addition, XPS data shows that the binding energy from these two compounds is 85.0 eV for Au (4f $\frac{7}{2}$), which is in agreement with other twocoordinate linear Au atoms in Au(I) complexes that contain alkynyl and isocyanide ligands.⁴ The above evidence demonstrates the presence of alkynyl(isocyanide)gold(I) units in **4a**,**b**, but the overall structures are not defined by the spectroscopic data. Two possible structures are the hexagonal cyclic structure [{MeC₆H₃- $3,5-(C \equiv CAu)_2(\mu-L-L)_3$] and the zigzag polymeric structure [{MeC₆H₃-3,5-(C=CAu)₂(μ -L-L)}_x]. The insolubility of the compounds suggests, but does not prove, the polymeric structure. We note that the planar hexagonal structure would contain a large cavity (it would be a 102-membered ring) and so interpenetration might still lead to polymer or oligomer formation.

The reaction of the digold(I) diacetylide complex [{3,5- $MeC_6H_3(C \equiv C - Au)_2 \mid_p | (2)$ with the diphosphine ligands shown in Scheme 3 yielded the complexes **5a**–**f**. These complexes were soluble in dichloromethane; therefore, the two-step synthesis procedure used for the diisocyanide complexes was not necessary. Analogous diphosphine complexes of gold acetylides derived from 1,3,5triethynylbenzene or 1,4-diethynylbenzene are insoluble and almost certainly have polymeric structures.^{4,11} The major difference in solubility suggests a nonpolymeric structure for complexes 5.

The IR spectra show the expected weak peak due to ν (C=C) at ca. 2120 cm⁻¹. The ¹H NMR spectra of each complex 5 gave singlet resonances for the methyl and aryl protons of the tolyl group as well as the expected resonances for the diphosphine ligand. In addition, the ³¹P NMR spectrum of each complex exhibits one singlet, indicating that there is only one species present and that the phosphine groups are equivalent. The NMR data are not consistent with polymer formation, and a simple digold(I) complex is not possible because the ring strain would be too great. The simplest structure consistent with the spectroscopic data is the "dimer" $[{MeC_6H_3-3,5-(C \equiv CAu)_2(\mu-L-L)}_2]$, but larger rings and even catenanes cannot be ruled out. Most of the complexes failed to give parent ions in the FAB-MS, but 5a gave a peak at m/z 1832 as expected for the dimer formulation.¹⁶ The flexibility of the diphosphine ligands allows formation of the dimers without significant ring strain, as indicated by consideration of molecular models or by molecular mechanics calculations, and, in the absence of a structure determination, we tentatively suggest that all complexes 5 have this structure.

Several conformations of the large rings (ring sizes: 5a, 24; 5b, 26; 5c, 28; 5d, 30; 5e, 32; 5f, 34) that result from dimer formation are possible. A favored conformation, based on molecular mechanics calculations and precedents, is the folded one shown in Scheme 3 for **5a**.¹⁷ However, the ¹H NMR spectrum of **5a** gave only one resonance for the CH₂P₂ protons, whereas the fixed, folded conformation would give two. No major change

⁽¹⁶⁾ Molecular weights of alkynylgold complexes by FAB-MS can be misleading due to aggregation or fragmentation in the spectrom-eter: Bruce, M. I.; Liddell, M. J. J. Organomet, Chem. **1992**, 427, 263 (17) Payne, N. C.; Ramachandran, R.; Puddephatt, R. J., Can. J. Chem. 1995, 73, 6.

Scheme 2

was observed in the low-temperature ¹H NMR, and so the rings must be able to reach a planar conformation,

 a In all cases $^{\lambda}{}_{\rm ex} = 350$ nm. b Insufficiently soluble for solution study.

in which there is a plane of symmetry containing the PCP atoms, sufficiently easily that the CH_2 protons appear equivalent. The ¹H NMR data of all complexes **5** display similar effective symmetry. Hence, if transannular Au···Au attractions are present in the folded structures, they must be weak.

Emission Spectra. A summary of the emission spectra is given in Table 3, and typical spectra are shown in Figure 3. All of the soluble complexes exhibited room-temperature emission as dichloromethane solutions, and all gave a single broad emission in the region 430–460 nm, similar to other alkynylgold(I) complexes.^{4,14,15,18} The solid-state emission spectra of these complexes all gave red-shifted bands compared to solution emission (Table 3), perhaps as a result of Au···Au interactions in the solid state.^{4,15,18} There were only minor differences in the emission energies or appearance of the emission spectra for the complexes with monodentate phosphite, phosphine, or isocyanide ligands and those containing bidentate phosphines (Table 3, Figure 3). However, in some cases the solid-state

⁽¹⁸⁾ Yam, V. W. W.; Lo, K. K. W. Chem. Soc. Rev. 1999, 28, 323.

Figure 3. Typical emission spectra: (top) complex **3c**; (bottom) complex **5c**. In each case, spectrum a is for a solution in dichloromethane and spectrum b is for the solid state.

emission spectra showed resolved fine structure, attributed to vibrational coupling, whereas in other cases they did not (Figure 3). For the phosphine complexes, the resolved bands were separated by ca. 1100 cm⁻¹, probably indicating coupling to an aryl vibrational mode. Following earlier discussion, the emission is tentatively assigned as arising from a $\sigma(AuC) - \pi^*$ excited state.^{4c} The close similarity between spectra for complexes containing monodentate phosphines (3c,d) and bidentate phosphines (5a-e) indicates that the methylene bridges in the diphosphine ligands prevent conjugation effects, which might lead to a red shift.^{4c} In contrast, the diisocyanide complexes **4a**,**b** give solidstate emissions that are red shifted compared to the mono-isocyanide complexes **3e**,**f** (Table 3), indicating that there is extended conjugation in the diisocyanide complexes.^{4c}

In summary, the angular 3,5-diethynyltoluene gives complexes with monodentate ligands that form onedimensional ribbon structures through Au····Au attractions in the solid state. With bidentate ligands, the rigid linear diisocyanides appear to give zigzag polymeric structures, whereas the more flexible diphosphines give ring structures. The emission spectra indicate that intermolecular Au····Au bonding is present in all complexes and that extended conjugation is present in the diisocyanide complexes.

Experimental Section

NMR spectra were collected by using a Varian Gemini 300 MHz spectrometer, and chemical shifts are referenced to TMS or phosphoric acid. IR spectra were recorded as Nujol mulls on KBr plates using a Perkin-Elmer 2000 FTIR. Mass spectra were recorded by using a Finnigan-MAT 8200 spectrometer. [AuCl(SMe₂)] and diisocyanoarenes were prepared by literature methods.^{19–21}

MeC₆**H**₃**·3**,**5·(C≡CH)**₂ (1). To a mixture of (trimethylsilyl)acetylene (5.89 g, 0.06 mmol) and *m*-dibromotoluene (5.0 g, 0.02 mmol) in piperidine (100 mL) were added Pd(PPh₃)₂Cl₂ (0.5 g) and CuI (0.2 g). The reaction mixture was stirred for 6 h at 90 °C under an atmosphere of N₂. Additional catalyst (as above) and (trimethylsilyl)acetylene (0.02 mmol) were added at this point, and the reaction mixture was heated and stirred for 6 h. The solvent was removed under reduced pressure, and the residue was then treated with aqueous KOH (20 mL, 1 M) and MeOH (100 mL) and the mixture refluxed overnight. After removal of methanol, the product was extracted with ether and then purified by chromatography on neutral alumina using hexane as a eluent to afford a clear light yellow oil. Yield: 0.50 g, 18%. NMR in CD₂Cl₂: δ (¹H) 2.31 [s, 3H, CH₃]; 3.13 [s, 2H, CCH]; 7.31 [s, 2H, *o*-H]; 7.42 [s, 1H, *p*-H]; δ (¹³C) 133.84, 133.56, 133.38, 133.02 [aryl], 78.16 [*C*=CH], 77.89 [*C*= *C*H], 30.18 [CH₃]. IR (Nujol, cm⁻¹): ν (CC–*H*) 3300, ν (C=C) 2117(s), 2224.9. MS: *m*/*z* found 140.062 71, calcd for C₁₁H₈ 140.062 60.

[{**MeC**₆**H**₃-3,5-(**C**=**CAu**)₂}_{*n*}] (2). *Caution! Shock-sensitive.* [AuCl(SMe₂)] (0.4 g, 1.36 mmol) was suspended in THF (50 mL). A solution of **1** (0.095 g, 0.68 mmol) and NaO₂CMe (0.11 g, 1.36 mmol) in THF (25 mL)/MeOH (15 mL) was added, and the resulting mixture was stirred for 3 h, yielding a bright yellow precipitate. The mixture was filtered and the yellow solid washed with THF, MeOH, and pentane and dried in vacuo. Yield: 0.32 g, 89%. The solid is insoluble in common organic solvents. IR (Nujol, cm⁻¹): ν (C=C) 1985 (w). Anal. Calcd for C₁₁H₆Au₂: C, 24.8; H, 1.1. Found C, 23.8; H, 1.1. The analysis is poor since the insoluble material cannot be further purified—further characterization is by formation of soluble derivatives described below. A sample of compound **2** exploded on scratching with a metal spatula.

[MeC₆H₃-3,5-{C≡CAuP(OPh)₃}₂] (3a). A mixture of **2** (0.22 g, 0.41 mmol) and P(OPh)₃ (0.24 g, 0.83 mmol) in dichloromethane (20 mL) was stirred for 30 min. The mixture was filtered to remove suspended material, and then pentane (100 mL) was added to the filtrate to give the product as a white solid, which was collected by filtration and washed with ether and pentane. Yield: 0.30 g, 63%. NMR in CD₂Cl₂: δ (¹H) 2.15 [s, 3H, CH₃], 6.94 [s, 2H, *o*-H], 6.98 [s, 1H, *p*-H], 7.29–7.45 [m, 30H, Ph]; δ (³¹P) 138.18 [s]. IR (Nujol, cm⁻¹): *ν*(C≡C) 2115 (w). Anal. Calcd for C₄₇H₃₆O₆P₂Au₂: C, 49.0; H, 3.1. Found: C, 49.3; H, 3.1.

[MeC₆H₃-3,5-{C≡CAuP(OMe)₃}₂] (3b). This was prepared similarly from **2** (0.20 g, 0.38 mmol) and P(OMe)₃ (0.081 g, 0.752 mmol). Yield: 0.20 g, 68%. NMR in CD₂Cl₂: δ ⁽¹H) 2.22 [s, 3H,CH₃], 7.05 [s, 2H, *o*-H], 7.15 [s, 1H, *p*-H], 3.76 [d, 18H, ²*J*(PH) = 16 Hz, CH₃]; δ ⁽³¹P) 150.34 [s]. IR (Nujol, cm⁻¹): ν (C≡C) 2120 (w). Anal. Calcd for C₁₇H₂₄O₂P₂Au₂: C, 26.2; H, 3.1. Found: C, 26.0; H, 3.1.

[MeC₆H₃-3,5-(C≡CAuPPh₃)₂]·0.5CH₂Cl₂ (3c). This was prepared similarly from **2** (0.20 g, 0.38 mmol) and PPh₃ (0.20 g, 0.76 mmol). Yield: 0.26 g, 65%. NMR in CD₂Cl₂: δ (¹H) 2.23 [s, 3H, CH₃], 7.09 [s, 2H, *o*-H], 7.21 [s, 1H, *p*-H], 7.5 [m, 30H, Ph]; δ (³¹P) 42.80 [s]. IR (Nujol, cm⁻¹): ν (C≡C) 2120 (w), 2212 (w). Anal. Calcd for C₄₇H₃₆P₂Au₂·0.5CH₂Cl₂: C, 51.9; H, 3.4. Found: C, 51.3; H, 3.4. The presence of dichloromethane was confirmed by ¹H NMR.

[MeC₆H₃-3,5-(C≡CAuPMePh₂)₂] (3d). This was prepared similarly from **2** (0.20 g, 0.38 mmol) and PMePh₂ (0.15 g, 0.76 mmol). Yield: 0.24 g, 67%. NMR in CD₂Cl₂: δ ⁽¹H) 2.22 [s, 3H, CH₃], 7.06 [s, 2H, *o*-H], 7.18 [s, 1H, *p*-H], 2.05 [d, 6H, ²*J*(PH) = 9.3 Hz, PMe], 7.4–7.7 [m, 20H, Ph]; δ ⁽³¹P) 25.17 [s]. IR (Nujol, cm⁻¹): ν (C≡C) 2120 (w), 2212 (w). Anal. Calcd for C₃₇H₃₂P₂Au₂: C, 47.7; H, 3.5. Found: C, 47.9; H, 3.4.

[MeC₆H₃-3,5-(C≡CAuCN-*t***-Bu)₂] (3e).** This was prepared similarly from **2** (0.10 g, 0.19 mmol) and *t*-BuNC (31.42 mg, 0.38 mmol). Yield: 0.062 g, 47%. NMR in CD₂Cl₂: δ (¹H) 2.21 [s, 3H, CH₃], 7.02 [s, 2H, *o*-H], 7.12 [s, 1H, *o*-H], 1.55 [s, 18H, Bu]. IR (Nujol, cm⁻¹): ν (C≡C) 2120 (w), ν (C≡N) 2229 (s). XPS: BE(Au 4f ⁷/₂) = 85.0 eV. Anal. Calcd for C₂₁H₂₄N₂Au₂: C, 36.1; H, 3.5; N, 4.0. Found: C, 36.0; H, 3.6; N, 3.9.

[MeC₆H₃-3,5-(C≡CAuCNMe)₂] (3f). This was prepared similarly from **2** (0.10 g, 0.19 mmol) and MeNC (15.52 mg, 0.38 mmol). Yield: 0.080 g, 69%. IR (Nujol, cm⁻¹): ν (C≡N) 2259 (s), ν (C≡C) 2120(w). XPS: BE(Au 4f⁷/₂) = 85.0 eV. Anal.

Structural Determination of 3b and 3d. Suitable crystals were mounted on thin, glass fibers using paraffin oil. Data were collected using a Bruker AX SMART 1K CCD diffractometer using 0.3° ω -scans at 0, 90, and 180° in ϕ . Crystal data and structure refinement details are given in Table 4. Unitcell parameters were determined from 60 data frames collected at different sections of the Ewald sphere. Semiempirical absorption corrections based on ψ scans were applied. Systematic absences in the diffraction data and unit-cell parameters were consistent with P1 and $P\overline{1}$ for **3b** and uniquely with $P2_1/c$ for **3d**. Solution in the centric space group for **3b** yielded computationally stable and chemically reasonable results of refinement. The structures were solved by direct methods, completed with difference Fourier syntheses, and refined with full-matrix least-squares procedures based on F^2 . For complex 3d, the aromatic groups were treated as rigid hexagons. All non-hydrogen atoms were refined with anisotropic displacement parameters. All hydrogen atoms were treated as idealized contributions. All scattering factors and anomalous dispersion factors are contained in the SHELXTL 5.10 program library (G. M. Sheldrick, Bruker AXS, Madison, WI, 1997).
