Diastereoselective Pd(II)-Catalyzed sp<sup>3</sup> C-H Arylation Followed by Ring Opening of Cyclopropanecarboxamides: Construction of *anti* β-Acyloxy Carboxamide Derivatives Bojan Gopalakrishnan, Sruthi Mohan, Ramarao Parella and Srinivasarao Arulananda Babu\* Department of Chemical Sciences, Indian Institute of Science Education and Research (IISER) Mohali, Manauli P.O., Sector 81, SAS Nagar, Mohali, Knowledge City, Punjab 140306, India sababu@iisermohali.ac.in

#### ABSTRACT

diastereoselective Pd(OAc)<sub>2</sub>-catalyzed, bidentate ligand-directed sp<sup>3</sup> C-H The activation/arylation followed by ring opening of cyclopropanecarboxamides, which were assembled from cyclopropanecarbonyl chlorides and bidentate ligands (e.g., 8-aminoquinoline and 2-(methylthio)aniline, has been investigated. The treatment of various cyclopropanecarboxamides with excess amounts of aryl iodides in the presence of the Pd(OAc)<sub>2</sub> catalyst, AgOAc and AcOH directly afforded the corresponding multiple  $\beta$ -C-H arylated open-chain carboxamides (anti  $\beta$ acyloxy amides). This method has led to the construction of several *anti*  $\beta$ -acyloxy amides that possess vicinal stereocenters with a high degree of stereocontrol with the formation of a new C-O bond and three new C-C bonds. A plausible mechanism for the formation of multiple β-C-H arylated open-chain carboxamides from the Pd-catalyzed, bidentate ligand-directed  $\beta$ -C-H arylation and the ring opening of cyclopropanecarboxamides is proposed based on several control experiments. The observed diastereoselectivity and *anti* stereochemistry of the  $\beta$ -acyloxy amides were ascertained based on X-ray structural analysis of representative  $\beta$ -acyloxy amides.

# **INTRODUCTION**

Cyclopropane is the smallest ring in the cycloalkane family and is regularly encountered in the core of numerous natural products and medicinally/biologically active molecules.<sup>1,2</sup> The chemistry of cyclopropanes is well understood, and cyclopropanes are one of the most versatile building blocks in organic synthesis.<sup>2-5</sup> In addition, the release of the inherent ring strain associated with the ring opening of the cyclopropane system has led to the discovery of numerous tandem transformations. In general, the ring-opening reaction pathways depend on the electronic nature of the functional groups or substituents that are present in the cyclopropane systems.<sup>1-5</sup>

Cyclopropenes,<sup>2a</sup> methylenecyclopropanes,<sup>3</sup> alkylidenecyclopropanes,<sup>3</sup> donor–acceptor cyclopropanes<sup>4</sup> and cyclopropyl ketones<sup>6a,b</sup> are the most important classes of compounds in the cyclopropane family. In general, cyclopropane systems readily undergo a wide range of transformations including cyclodimerizations, cycloadditions, rearrangements, and ring-opening (C-C cleavage) reactions under the influence of a variety of chemical reagents and suitable catalysts.<sup>1-5</sup> The chemistry, usefulness and different modes of ring cleavage of these individual classes of cyclopropane systems have been well documented and summarized in various reviews.<sup>1-</sup>

Although several types of cyclopropane ring-opening reactions are popularly known, the transition metal-catalyzed/promoted activation of the C-C bond and cleavage of the cyclopropane ring has received unique attention.<sup>2,3,5</sup> The relevant reviews by Cramer,<sup>5c</sup> Rubin/Gevorgyan,<sup>2a</sup> Pellissier,<sup>3a,b</sup> Brandi,<sup>3c</sup> Shi<sup>3d,e</sup> and Marek<sup>3f</sup> provide an overview of transition metal-catalyzed/promoted activation and modes of cleavage of the C-C bonds of substituted cyclopropanes, cyclopropenes, methylenecyclopropanes and alkylidenecyclopropanes, leading to ring-opening reactions. For the reactions involving cyclopropanes, "the strain-driven oxidative addition of the C-C bond of cyclopropanes to a transition-metal leads to the formation of metallacyclobutane, which was shown to open the way to different reaction".<sup>5c</sup> For the reactions

## The Journal of Organic Chemistry

involving cyclopropenes, methylenecyclopropanes and alkylidenecyclopropanes, "an unsaturated tether facilitates the activation of the cyclopropane and directs the metal toward the cleavable C–C bond and can also participate in the post-activation transformation".<sup>5c</sup> Representative transition metal-catalyzed/promoted reactions consisting of activation and cleavage of the C-C bonds of cyclopropane, methylenecyclopropane and alkylidenecyclopropane are shown in Figure 1.<sup>6-9</sup> Some of the transition metal-catalyzed/promoted reactions for donor–acceptor cyclopropane systems (activated cyclopropanes) are also shown in Figure 1.

selected transition metal-based ring-opening reactions of different classes of cyclopropane systems

Figure 1. Representative Metal-Catalyzed/Promoted Ring Opening Reactions of Cyclopropane Systems.

Transition metal-catalyzed C-H activation/functionalization reactions have received significant attention in recent years, and in general, C-H functionalization-based cross-coupling reactions are considered to be step-economical organic transformations.<sup>10-14</sup> Among the transition metal catalysts, the Pd(II) catalysts are frequently employed to perform  $sp^2$  and  $sp^3$  C-H activation/functionalization reactions.<sup>10-14</sup> Although the directing group-assisted or directing group-free sp<sup>2</sup> C-H activation/functionalization reactions have been extensively studied, the sp<sup>3</sup> C-H activation/functionalization reactions have received much attention after the seminal reports by Daugulis,<sup>12a,13a</sup> Yu<sup>11b,13b,c</sup> and other distinguished research groups.<sup>10-14</sup> Therefore, in recent years, the research area pertaining to the directing group-aided sp<sup>3</sup> C–H activation/functionalization of aliphatic/alicyclic carboxamides remains active.<sup>10-16</sup> Although sp<sup>3</sup> C–H activation/functionalization was investigated using a variety of aliphatic/alicyclic substrates, it is important to note that cyclopropane, which is the smallest carbocyclic ring, was also successfully subjected to the Pd(II)catalyzed C-H activation/functionalization.<sup>15</sup> In this regard, our group recently reported the diastereoselective Pd(II)-catalyzed. bidentate ligand-directed β-C-H arylation of cyclopropanecarboxamide derivatives.<sup>16g</sup>

Inspired by the transition metal-catalyzed ring opening of cyclopropanes including the C-H/C-C bond activation strategy<sup>2a,3,5-9</sup> as well as our previous work,<sup>16g</sup> we envisioned a one-pot method involving Pd(II)-catalyzed, bidentate directing group-aided  $\beta$ -C-H arylation followed by ring opening of cyclopropanecarboxamide derivatives. Accordingly, the reaction of unsubstituted cyclopropanecarboxamide **1** with excess amounts of aryl iodide **2** in the presence of Pd(OAc)<sub>2</sub> as a catalyst, AgOAc and AcOH as the additive afforded the open-chain carboxamide derivatives **5**/6 with a high degree of stereocontrol (Scheme 1). Herein, the results from our investigations including a plausible mechanism for the formation of the open-chain carboxamide derivatives **5**/6 from the Pd(II)-catalyzed C-H arylation followed by ring opening of cyclopropanecarboxamides **1** are reported.

Scheme 1. Diastereoselective Pd(II)-Catalyzed C-H Arylation Followed by Ring Opening of Cyclopropanecarboxamides 1.

stereoselective C-H activation / arylation followed by ring-opening of cyclopropanes

# **RESULTS AND DISCUSSION**

To initially explore the Pd(II)-catalyzed C-H arylation followed by ring opening of cyclopropanecarboxamides, we performed optimization reactions using unsubstituted cyclopropanecarboxamide **1a**, which was prepared from the 2-aminothioanisole bidentate ligand. Table 1 shows the results for the Pd(OAc)<sub>2</sub>–catalyzed reaction of **1a** with excess amounts of *p*-tolyl iodide in the presence of various additives. Upon treatment of cyclopropanecarboxamide **1a** with excess amounts of *p*-tolyl iodide in the presence of the Pd(OAc)<sub>2</sub> catalyst and AgOAc, we expected that compound **1a** would undergo mono/bis C-H arylation followed by ring opening to afford the corresponding open-chain carboxamide derivatives. Accordingly, the reaction of **1a** (0.25 mmol) with excess amounts of *p*-tolyl iodide (0.38-2.0 mmol) in the presence of the Pd(OAc)<sub>2</sub> catalyst and AgOAc afforded bis-arylated cyclopropanecarboxamide **3a** (yields up to 37%) and mono-arylated cyclopropanecarboxamide **4a** (yields up to 40%) along with anticipated ring-opened product **5a** (yields up to 20%, entries 1-7, Table 1).

To obtain ring-opened product **5a** as the major compound in satisfactory yield, we performed the Pd(II)-catalyzed reaction of **1a** with **2a** in the presence of additional additives (e.g., Na<sub>2</sub>SO<sub>4</sub>, NaOAc and KOAc). These reactions also afforded the corresponding three products (**3a**, **4a** and **5a**) without much selectivity (entries 8-12, Table 1). Next, we performed the Pd(II)-catalyzed reaction of **1a** with **2a** in the presence of PivOH or TfOH, which was also ineffective (entries 13 and 14, Table 1). Fortunately, the Pd(OAc)<sub>2</sub>/AgOAc catalytic system-based reaction of

#### The Journal of Organic Chemistry

**1a** with excess amounts of aryl iodide **2a** in the presence of AcOH directly afforded multiple  $\beta$ -C-H arylated open-chain carboxamide (*anti*  $\beta$ -acyloxy amide<sup>17a,b</sup>) **5a** in 47-86% yields (entries 15-19, Table 1). It is important to note that this process, which consists of the Pd(OAc)<sub>2</sub>/AgOAc-catalytic system-based reaction of **1a** with excess amounts of aryl iodide **2a** in the presence of AcOH, has led to the construction of *anti*  $\beta$ -acyloxy amide **5a**,<sup>18</sup> possessing vicinal stereocenters with a high degree of stereocontrol with the formation of a new C-O bond and three new C-C bonds.

After determining the suitable reaction conditions for obtaining multiple  $\beta$ -C-H arylated open-chain carboxamide 5a from 1a, we investigated the generality of this protocol and performed the diastereoselective C-H arylation followed by ring opening of substrate **1a** using various aryl iodides (Table 2). Using the optimized reaction conditions (entry 19, Table 1), we performed the Pd(OAc)<sub>2</sub>/AgOAc catalytic system-based diastereoselective C-H arylation followed by ring opening of substrate 1a with different aryl iodides, which furnished the corresponding multiple  $\beta$ -C-H arylated open-chain carboxamides (*anti*  $\beta$ -acyloxy amides) **5a-l** in 10-86% yields (Table 2). We observed that the C-H arylation followed by ring opening of substrate 1a proceeded smoothly and afforded products 5a-h and 5l when the Pd(II)-catalyzed reaction of substrate 1a was performed with any iodides that possessed electron-donating alkyl groups (e.g., Me, Et and  $^{i}$ Pr) at the para or meta position of the aryl ring in the aryl iodides. However, we experienced some difficulty when the Pd(II)-catalyzed C-H arylation reaction of substrate 1a was performed with aryl iodides that possessed electron-withdrawing groups (i.e., Br, F and NO<sub>2</sub>) at the para or meta position of the aryl ring in the aryl iodides. Therefore, the Pd(OAc)<sub>2</sub>/AgOAc catalytic systembased reaction of substrate 1a with aryl iodides possessing electron-withdrawing groups afforded corresponding products **5i-k** in low yields. Although a clear reason is not known at this stage, we assume that the aryl iodides that possess electron-withdrawing groups may be less reactive than aryl iodides containing alkyl groups under our experimental conditions.

Next, we investigated diastereoselective C-H arylation followed by ring opening of cyclopropanecarboxamide using cyclopropanecarboxamide **1b**, which was assembled from 8-aminoquinoline bidentate ligand (Table 3). The Pd(OAc)<sub>2</sub>/AgOAc catalytic system-based diastereoselective C-H arylation followed by ring opening of cyclopropanecarboxamide **1b** with

different aryl iodides in AcOH afforded the corresponding multiple  $\beta$ -C-H arylated open-chain carboxamides **6a-e** (*anti*  $\beta$ -acyloxy amides possessing vicinal stereocenters) in 20-75% yields (Table 3). In these studies, we have revealed the concept of Pd(II)-catalyzed C-H arylation followed by ring opening of cyclopropanecarboxamides using unsubstituted cyclopropanecarboxamides **1a** and **1b** as the substrates. Next, we examined the Pd(II)-catalyzed C-H arylation followed by ring opening of cyclopropanecarboxamides using various mono-arylated cyclopropanecarboxamides **4a**/**8**/**9**/**13**/**14**/**15b** (*cis* isomers) and **15a** (*trans* isomer) as the substrates (Scheme 2).

Table 3.18Pd(II)-CatalyzedC-HArylationFollowedbyRingOpeningofCyclopropanecarboxamide 1b.

The Pd(II)-catalyzed C-H arylation followed by ring opening of *cis* cyclopropanecarboxamides **8** and **9** with aryl iodides **2c/2b** furnished the corresponding multiple  $\beta$ -C-H arylated open-chain carboxamides **5c** (61%) and **5b** (39%, Scheme 2). It is important to note that the substituents present at the *para* positions of the respective aryl iodides (**2c/2b**) and the substituents present at the *para* positions of the aryl rings of the respective substrates (**8**/**9**) were

identical. Therefore, the Pd(II)-catalyzed C-H arylation followed by ring opening of **8/9** with **2c/2b** furnished corresponding products **5c** and **5b**, in which the corresponding aryl rings had identical substituents at the *para* positions. Similar to the reactions involving substrates **8** and **9**, the Pd(II)-catalyzed C-H arylation followed by ring opening of the *cis* cyclopropanecarboxamides **13** and **14** with *para*-substituted aryl iodides **2a** and **2b** afforded the corresponding multiple  $\beta$ -C-H arylated open-chain carboxamides **6d** (51%) and **6a** (57%, Scheme 2). Additionally, the Pd(II)-catalyzed C-H arylation followed by ring opening of the *trans* cyclopropanecarboxamide **15a** with iodobenzene also furnished multiple  $\beta$ -C-H arylated open-chain carboxamides **5b** in 30% yield (Scheme 2).<sup>18c</sup>

Scheme 2.<sup>18</sup> Pd(II)-Catalyzed C-H Arylation Followed by Ring Opening of Cyclopropanecarboxamides 4a, 8, 9, 13, 14 and 15a,b.<sup>a</sup>

<sup>a</sup> The reactions were performed using the corresponding carboxamide (0.25 mmol) and ArI (1.2 mmol). <sup>b</sup> This reaction was performed using carboxamide **15b** (0.25 mmol) and ArI (2 mmol).

#### The Journal of Organic Chemistry

The Pd(II)-catalyzed arylation C-H followed by ring opening of cis cyclopropanecarboxamides 4a and 8 with the corresponding aryl iodides 2a-c and 2l furnished the respective multiple  $\beta$ -C-H arylated open-chain carboxamides **10,11** (43-60%) and **12a-c** (52-63%). Scheme 2).<sup>18</sup> It is important to note that the substituents present at the *para/meta* positions of the respective aryl iodides **2a-c** and **2l** and the substituents present at the *para* positions of the aryl rings of the respective substrates 4a and 8 were not identical. Therefore, the Pd(II)-catalyzed C-H arylation followed by ring opening of 4a and 8 with 2a-c and 2l furnished corresponding products 10,11 and 12a-c, in which the corresponding aryl rings did not contain identical substituents at the para positions.<sup>18</sup> Along this line, the Pd(II)-catalyzed C-H arylation followed by ring opening of cis cyclopropanecarboxamide 15b with 2a furnished the respective multiple  $\beta$ -C-H arylated openchain carboxamide 12d in 26% yield (Scheme 2). The structure and stereochemistry of compound 12d were unambiguously established based on X-ray structure analysis (see SI for the X-ray structure of the compound 12d).

We also performed synthetic transformations to remove the directing groups from the representative multiple  $\beta$ -C-H arylated open-chain carboxamides that were obtained from the Pd(II)-catalyzed C-H arylation followed by ring opening of cyclopropanecarboxamide. Initially, we attempted the amide hydrolysis reaction of *anti*  $\beta$ -acyloxy amide **6d** with 12 equiv of NaOH in EtOH, and this reaction afforded carboxamide **16a**, which contain the directing group, and carboxylic acid **17a** (formed from carboxamide **16a**, Scheme 3). Similarly, the amide hydrolysis reaction of *anti*  $\beta$ -acyloxy amide **5l** with 12 equiv of NaOH in EtOH afforded carboxamide **16b**, and carboxylic acid **17b** (formed from carboxamide **16b**, Scheme 3). Then, the treatment of *anti*  $\beta$ -acyloxy amide **5a** with less NaOH (6 equiv) in EtOH only furnished carboxamide **16c**, and in this case, the corresponding carboxylic acid was not detected. In addition, we reacted carboxamides **10**, **11** and **12b,c** possessing different aryl groups at the 1,3-positions with less NaOH (6 equiv) to afford corresponding carboxamides **16b, d,e** (Scheme 3).

Next, the amide hydrolysis reaction was investigated under mild reaction conditions. We performed the amide hydrolysis of *anti*  $\beta$ -acyloxy amide **5a** in the presence of K<sub>2</sub>CO<sub>3</sub> in MeOH, and this reaction afforded  $\beta$ -hydroxy amide **18a** and carboxamide **16c**.<sup>17c</sup> In addition, the reaction of *anti*  $\beta$ -acyloxy amide **5a** in the presence of LiAlH<sub>4</sub> afforded carboxamide **16c**. We also attempted the amide hydrolysis and removal of the directing groups (i.e., 8-aminoquinoline and 2-(methylthio)aniline) under acidic conditions. However, these trials were not fruitful at this stage

#### The Journal of Organic Chemistry

(see the SI for further trials in this regard). In the base-mediated amide hydrolysis reactions of the substrates investigated in Scheme 3, we expected the removal of the directing groups (i.e., 8-aminoquinoline and 2-(methylthio)aniline) as well as the deprotection of the OAc group present in the corresponding substrates. However, because the products (5/6/10-12) obtained from the Pd(II)-catalyzed C-H arylation followed by ring opening of cyclopropanecarboxamides were aldol-type derivatives, these compounds readily underwent retro-aldol type reactions<sup>17b,c</sup> even under mild or strongly basic conditions and furnished corresponding products **16** under the experimental conditions.<sup>17e</sup>

Because the Pd-catalyzed reaction of cyclopropanecarboxamides with aryl iodides in AcOH affords the corresponding open-chain carboxamides 5/6/10-12, control experiments were performed to determine a plausible mechanism for the formation of products 5/6/10-12 from their corresponding cyclopropanecarboxamide substrates shown in Tables 1-3 and Scheme 2. Initially, attempted the Pd(II)-catalyzed C-H arylation followed by ring opening of we cyclopropanecarboxamides 1d and 1e, which contain no directing groups. and cyclopropanecarboxamides 1f and 1g, which were prepared using other bidentate ligands. The Pd(II)-catalyzed C-H arylation followed by ring opening of substrates 1d-g failed to yield the corresponding  $\beta$ -acyloxy amides (Scheme 4). These reactions revealed that 8-aminoquinoline and 2-(methylthio)aniline were efficient bidentate ligands and essential for accomplishing the Pd(II)catalyzed C-H arylation followed by ring opening of the respective cyclopropanecarboxamides shown in Tables 1-3 and Scheme 2.

Then, we performed control experiments to understand at what stage the C-C cleavage of the corresponding cyclopropanecarboxamides occurs and how the open-chain carboxamides 5/6/10-12 are formed with a high degree of stereocontrol. Initially, we performed the control experiments using unsubstituted cyclopropanecarboxamide **1a**. The reaction of **1a** with only the Pd(OAc)<sub>2</sub> catalyst, AgOAc and AcOH did not yield  $\beta$ -acyloxy amide **20** (i.e., the expected open-

chain compound, entry 1, Scheme 4). The treatment of **1a** with only AgOAc and AcOH did not yield compound **20** (entry 2, Scheme 4). In addition, the reaction of **1a** with only AcOH did not yield expected compound **20** (entry 3, Scheme 4, see the SI for the crude NMR spectra of the reactions of compound **1a**).

# Scheme 4. Screening of Other Ligands and Control Experiments Performed using Substrate

**1a.**<sup>a</sup>

<sup>a</sup> See the SI for the crude NMR spectra of the reactions of compound **1a**.

Next, we performed control experiments using bis-arylated cyclopropanecarboxamide **3b**. We assembled compound **3b**, which was subjected to a Pd(II)-catalyzed C-H arylation reaction with iodobenzene in the presence of AcOH (Scheme 5). This reaction resulted in the formation of product **5b**, which was directly obtained from **1a** (entry 19, Table 2). The reaction of **3b** with only the Pd(OAc)<sub>2</sub> catalyst, AgOAc and AcOH afforded expected open-chain compound **21**, which was isolated in 25% yield and characterized (entry 1, Scheme 5). The treatment of **3b** with only

AgOAc and AcOH did not yield compound **21** (entry 2, Scheme 5). Similarly, the reaction of **3b** with only AgOAc or AcOH also did not yield compound **21** (entries 3 and 4, Scheme 5). Next, we performed a control experiment involving the C-H arylation reaction of **21** with PhI in the presence of the Pd(OAc)<sub>2</sub> catalyst and AgOAc, which resulted in the formation of **5b** (Scheme 5, see the SI for the crude NMR spectra for the reactions of compounds **3b** and **21**).

<sup>a</sup> See the SI for the crude NMR spectra of the reactions of compounds **4a**, **9**, **13**, **14** and **22**. <sup>b</sup> The reaction time was 48 h. <sup>c</sup> This reaction was performed using **4a** (0.125 mmol) rather than **9** and 1 mL of AcOH.

Although we performed the control reactions using unsubstituted cyclopropanecarboxamide **1a** and bis-arylated cyclopropanecarboxamide **3b**, based on the results shown in Scheme 2, we envisioned that the ring opening can also occur after the mono-arylation of

#### The Journal of Organic Chemistry

**1a** (or before the bis-arylation of **1a**). To validate this hypothesis, control experiments were performed using mono-arylated cyclopropanecarboxamides **9** and **14** (Scheme 6). The reaction of substrates **9** and **14** with only the Pd(OAc)<sub>2</sub> catalyst, AgOAc and AcOH yielded the corresponding open-chain compounds (i.e., **22** (33%) and **23a** (43%)), which were isolated and characterized (entries 1 and 2, Scheme 6). Then, a control experiment involving the C-H arylation reaction of **22** with PhI in the presence of the Pd(OAc)<sub>2</sub> catalyst and AgOAc resulted in the formation of **5b**, which was obtained directly from **1a** (entry 19, Table 2). Then, additional control experiments were performed using substrates **9/14** by varying the control reagents (entries 3-7, Scheme 6). However, none of these reactions afforded the corresponding compounds **22** and **23a**. A control experiment involving the reaction of **14** with only the Pd(OAc)<sub>2</sub> catalyst and AcOH afforded openchain compound **23a** (entry 8, Scheme 6). In addition, the reaction of **13** with only the Pd(OAc)<sub>2</sub> catalyst and AcOH afforded openchain compound **23b** with **2c** in the presence of the Pd(OAc)<sub>2</sub> catalyst and AgOAc afforded compound **12e** (47%, Scheme 6). It is important to note that the substituent present at the *para* position of **2c** and the substituent present at the *para* position of the arylaring of **23b** were not the same.

The formation of compounds 22/23a from the reactions of respective substrates 9/14 with the  $Pd(OAc)_2$ catalyst, AgOAc and AcOH indicated that mono-arylated only cyclopropanecarboxamides 9/14 and ring-opened carboxamides 22/23a were possible intermediates in the reaction of 1a/1b with PhI in the presence of the Pd(OAc)<sub>2</sub> catalyst, AgOAc and AcOH. This hypothesis was further validated from the Pd(OAc)<sub>2</sub>-catalyzed double C-H arylation reaction of the methyl group of 22 with PhI, which yielded compound 5b (see the SI for the crude NMR spectra for the reactions of compounds 4a, 9, 13, 14, 22 and 23b). Based on the results from the control reactions (Schemes 4-6) as well as observed products 5/6/10-12 (anti βacyloxy amides), we propose a plausible mechanism for the diastereoselective Pd(II)-catalyzed C-H arylation followed by ring opening of cyclopropanecarboxamides in Scheme 7. The mechanism is proposed on the basis of the generally accepted Pd(II/IV) catalytic cycle mechanism<sup>19</sup> involving bidentate ligand-aided C-H arylation. Based on the control experiments (Schemes 4-6), we have elucidated a possible mechanism for the formation of *anti*  $\beta$ -acyloxy amide **5b** from the Pd(II)catalyzed reaction of **1a** with PhI in the presence of AgOAc and AcOH. The C-C cleavage of the cyclopropane ring is predicted to only occur after the formation of mono-arylation product **9** as well as bis-arylation product **3b**. For the C-C bond cleavage process, both the Pd(OAc)<sub>2</sub> catalyst and AcOH are essential. However, AgOAc is not essential for the C-C bond cleavage process, and AgOAc simply helps to regenerate the Pd(OAc)<sub>2</sub> catalyst in the C-H arylation process involved in the Pd(II/IV) catalytic cycle mechanism.<sup>19</sup>

Under the current experimental conditions, compound **3b** or **9** is also expected to be present as **24a**. Then, due to the ring strain, the mono or bis C-H arylated cyclopropanecarboxamide system **24a** undergoes C-C cleavage through (a) a  $S_N 2$  type internal attack by the OAc group of the Pd(II) species **24a** or (b) an AcOH-influenced Pd-based C-C activation/C-C bond cleavage<sup>15a</sup> involving a  $S_N 2$  type attack by the OAc group of AcOH (as shown in species **24b**). Both of these possibilities could form any one of the plausible intermediates **24c/24d/24e** with a high degree of stereocontrol. It is important to note that the stereochemistry of the OAc and CONH groups were determined to be *anti* in the X-ray structures (e.g., **5b**, **6c** and **6d**). Notably, the C-H arylation of cyclopropanecarboxamides has been reported to be a stereoselective process,<sup>16g,19</sup> and in the current study, the ring opening of the cyclopropanecarboxamides was determined to be a stereoselective process.

The formation of compounds 21 (entry 1, Scheme 5) and 22 (entry 1, Scheme 6) from 3b or 9 confirmed the involvement of the plausible ring-opened intermediates 24c/24d/24e in the proposed mechanism. If intermediates 24c-e were not quenched by AcOH, a further C-H arylation of intermediates 24c/24d/24e (R = H/Ph) affords product 5b.<sup>19,20</sup> However, starting from 9 (R = H), if compound 22 was formed after the ring opening and before any further C-H arylation due to

#### The Journal of Organic Chemistry

the AcOH-mediated quenching of 24c/24d/24e (when R = H), the double C-H arylation of the methyl group of 22 would afford compound 5b (based on the control reaction shown in Scheme 6). Similarly, starting from 3b (R = Ph), if compound 21 was formed after the ring opening and before any further C-H arylation due to the AcOH-mediated quenching of 24c/24d/24e (when R = Ph), the C-H arylation of the methylene group of 21 would afford compound 5b (based on the control reaction shown in Scheme 5). Moreover, the second arylation of 9 may be a slow reaction due to the formation of the corresponding sterically crowded trisubstituted cyclopropanecarboxamide 3b. Therefore, the ring opening of 9 may occur before the C-H arylation to afford 5b *via* 24a-e (based on the control reaction shown in Scheme 6). Furthermore, starting from 1a, product 5b may have been directly formed from 9 rather than 3b.

Finally, based on these discussions and the formation of ring-opened carboxamide **23b** from the reaction of **13** with only the Pd(OAc)<sub>2</sub> catalyst, AgOAc and AcOH (Scheme 6) as well as the subsequent formation of **12e** from the Pd(OAc)<sub>2</sub>-catalyzed double C-H arylation of the methyl group of **23b** with **2c** indicated the following conclusions. First, the proposed structures of compounds **10**, **11**, **12a-d** (Scheme 2) have been confirmed. Second, the arylation of **8/4a/15b** with the respective aryl iodides **2a-c,l** may involve the corresponding ring-opened product similar to **23b** as the potential predominantly formed intermediates. In addition, because the second arylation of **8/4a/15b** may be a slow reaction due to the formation of the corresponding sterically crowded trisubstituted cyclopropanecarboxamide (e.g., compound type **3b**), we believe that the ring opening of **8/4a/15b** may occur prior to the C-H arylation of **8/4a/15b**. Therefore, although the respective arylation reactions of **8/4a/15b** with **2a-c** and **2l** are expected to afford more than one isomer, the respective arylation reactions of **8/4a/15b** with **2a-c** and **2l** yielded the respective compounds **10-12** (Scheme 2) as the predominant compounds.

Scheme 7.<sup>19</sup> Plausible Mechanism for the Diastereoselective Pd(II)-Catalyzed C-H Arylation Followed by Ring Opening of Cyclopropanecarboxamides.

#### CONCLUSION

Our studies have demonstrated Pd(OAc)<sub>2</sub>-catalyzed, bidentate ligand-directed sp<sup>3</sup> C-H activation/arylation followed by ring opening of cyclopropanecarboxamides. The treatment of various cyclopropanecarboxamides with excess amounts of aryl iodides in the presence of the Pd(OAc)<sub>2</sub> catalyst, AgOAc and AcOH directly afforded the corresponding multiple  $\beta$ -C-H arylated open-chain carboxamides (*anti*  $\beta$ -acyloxy amides). This method has led to the construction of several *anti*  $\beta$ -acyloxy amides that possess vicinal stereocenters with a high degree of stereocontrol with the formation of a new C-O bond and three new C-C bonds. Based on various control experiments, a plausible mechanism has been proposed for the formation of multiple  $\beta$ -C-H arylated open-chain carboxamides from the diastereoselective Pd-catalyzed, bidentate ligand-directed  $\beta$ -C-H arylation and ring opening of cyclopropanecarboxamides. The observed diastereoselectivity and *anti* stereochemistry of the obtained products were confirmed by X-ray structure analysis of representative  $\beta$ -acyloxy amides.

#### **EXPERIMENTAL SECTION**

**General.** The melting points of the compounds were uncorrected, and the IR spectra of the products were recorded as thin films or KBr pellets. The <sup>1</sup>H and <sup>13</sup>C{<sup>1</sup>H} NMR spectra of all of the compounds were recorded on 400 MHz and 100 MHz spectrometers, respectively, using TMS as an internal standard. The HRMS measurements of the samples were obtained from QTOF mass analyzer using the electrospray ionization (ESI) method. Column chromatography was performed using neutral alumina (in some cases, silica gel 100-200 mesh was used). The cyclopropanecarboxamides that were employed in the Pd(II)-catalyzed C-H arylation reactions were prepared from their corresponding acid chlorides and amines using standard literature procedures. The reactions were performed in anhydrous solvents, which were prepared using standard procedures, under a nitrogen atmosphere. The isolated yields of all of the compounds are

reported, and the yields were not optimized. In most cases, the purification of the crude reaction mixtures yielded only the major diastereomer in pure form and did not afford any other characterizable compounds. Compounds **1a**,<sup>16g</sup> **1b**,<sup>16g</sup> **1d**,<sup>21a</sup> **1g**,<sup>15c</sup> **3b**,<sup>16g</sup> **15a/15b**,<sup>16g</sup> **13**,<sup>16g</sup> **14**,<sup>16g</sup> **16d**,<sup>19b</sup> and **17a**<sup>21b</sup> have been previously reported in the literature.

**General procedure for the preparation of 1a,b/1d-g/15a:** To a dry round bottom (RB) flask, an appropriate ligand/amine (1 mmol), triethyl amine (1.1 mmol) and DCM (6 mL) were added under a nitrogen atmosphere. To this solution, the corresponding acid chloride (1 mmol) was added dropwise at 0 °C. The resulting mixture was stirred at room temperature for 20 h. After the reaction period, the mixture was diluted with DCM (2 x 10 mL) and transferred to a separatory funnel, and the DCM solution was washed with water followed by an aq. NaHCO<sub>3</sub> solution (2-5 mL). The organic layer was separated, dried over anhydrous Na<sub>2</sub>SO<sub>4</sub> and concentrated under vacuum, and purification of the crude reaction mixture by column chromatography (EtOAc/hexane) furnished products **1a,b/1d-g/15a**.

General procedure for the Pd(II)-catalyzed C-H arylation/ring opening of 1a/1b and the preparation of 5a-l/6a-e: To an oven dried RB flask, an appropriate cyclopropanecarboxamide (0.25 mmol, 1 equiv), the corresponding aryl iodide (2 mmol, 8 equiv), Pd(OAc)<sub>2</sub> (5.6 mg, 10 mol%, 0.1 equiv), AgOAc (125 mg, 0.75 mmol, 3 equiv), AcOH (0.25 mL) and anhydrous toluene (2-3 mL) were added, and the reaction mixture was refluxed at 110 °C for 16-36 h under a nitrogen atmosphere. After the reaction period, the reaction mixture was diluted with EtOAc (15-20 mL), transferred to a separatory funnel and washed with a dilute aq. NaHCO<sub>3</sub> solution (2-5 mL). The organic layer was separated, dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated under vacuum, and purification of the reaction crude mixture by column chromatography on neutral alumina furnished the corresponding multiple C-H arylated aliphatic carboxamides **5a-l/6a-e** (β-acyloxy amide derivatives) (see the corresponding Tables/Schemes for specific examples).

**General procedure for the Pd(II)-catalyzed mono C-H arylation of 1a/1b and the preparation of 4a/8/9/13/14/15b:**<sup>16g</sup> To an oven dried RB flask, an appropriate cyclopropanecarboxamide (1.0 mmol, 1 equiv), the corresponding aryl iodide (4 mmol, 4 equiv), Pd(OAc)<sub>2</sub> (11.2 mg, 5 mol%, 0.05 equiv), AgOAc (367 mg, 2.2 mmol, 2.2 equiv) and anhydrous toluene (6-8 mL) were added, and the reaction mixture was refluxed at 110 °C for 15 h under a nitrogen atmosphere. After the reaction period, the reaction mixture was concentrated under vacuum, and purification of the resulting reaction mixture by column chromatography on neutral alumina furnished the corresponding carboxamides **4a/8/9/13/14/15b**.

General procedure for the Pd(II)-catalyzed bis C-H arylation of 1a and the preparation of **3b**:<sup>16g</sup> To an oven dried RB flask, cyclopropanecarboxamide **1a** (1.0 mmol, 1 equiv), iodobenzene (10 mmol, 10 equiv), Pd(OAc)<sub>2</sub> (22.4 mg, 10 mol%, 0.1 equiv), AgOAc (367 mg, 2.2 mmol, 2.2 equiv) and anhydrous toluene (6-8 mL) were added, and the reaction mixture was refluxed at 120 °C for 20 h under a nitrogen atmosphere. After the reaction period, the reaction mixture was concentrated under vacuum, and purification of the resulting reaction mixture by column chromatography on neutral alumina furnished the corresponding carboxamide **3b** (careful repetitive purification was performed to obtain the pure compound **3b**).

General procedure for the Pd(II)-catalyzed C-H arylation/ring-opening of 4a/8/9/13-15 and the preparation of 5c,b/6a,d/10/11/12a-d: To an oven dried RB flask, an appropriate cyclopropanecarboxamide (0.25 mmol, 1 equiv), the corresponding aryl iodide (1.5 mmol, 6 equiv), Pd(OAc)<sub>2</sub> (5.6 mg, 10 mol%, 0.1 equiv), AgOAc (92 mg, 0.55 mmol, 2.2 equiv), AcOH (0.25 mL) and anhydrous toluene (2-3 mL) were added, and the reaction mixture was refluxed at 110 °C for 24-48 h under a nitrogen atmosphere. After the reaction period, the reaction mixture was diluted with EtOAc (15-20 mL), transferred to a separatory funnel and washed with a dilute aq. NaHCO<sub>3</sub> solution (2-5 mL). The organic layer was separated, dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated under vacuum, and purification of the reaction crude mixture by column

chromatography on neutral alumina furnished the corresponding multiple C-H arylated aliphatic carboxamides **5c,b/6a,d/10/11/12a-d** (β-acyloxy amide derivatives).

General procedure for the  $K_2CO_3$ -mediated hydrolysis carboxamide 5a and the preparation of 18a/16c: To a RB flask (with a capacity of 25 mL) fitted with a condenser, a solution of carboxamide 5a (0.25 mmol) dissolved in a mixture of methanol (2.5 mL), water (0.5 mL) and  $K_2CO_3$  (69 mg, 2 equiv) were sequentially added. The reaction mixture was heated at 80 °C for 12 h in an open atmosphere. Then, the reaction mixture was transferred to a separatory funnel with the aid of a syringe. The reaction mixture was diluted with ethyl acetate and washed with a dilute aq.  $Na_2CO_3$  solution (5-10 mL). The combined organic layers were separated and concentrated under vacuum, and purification of the reaction mixture on neutral alumina furnished products 18a/16c.

General procedure for the LiAlH<sub>4</sub>-mediated reduction of carboxamide 5a and the preparation of 16c: To a dry RB flask containing carboxamide 5a (0.125 mmol, 1 equiv) in THF (3 mL), LiAlH<sub>4</sub> (10 mg, 0.25 mmol, 2 equiv) was added at 0 °C. Then, the reaction mixture was warmed to room temperature and stirred for a total period of 15 h. After this period, the THF was evaporated, and the reaction mixture was diluted with EtOAc and water. Then, the reaction mixture was transferred to a separatory funnel, and the layers were separated. The organic layer was concentrated under vacuum, and purification of the reaction mixture on neutral alumina furnished products 16c.

General procedure for the NaOH–mediated hydrolysis of carboxamides 5a,l/6d/10/11/12b,c: To a RB flask (with a capacity of 25 mL) fitted with a condenser, a solution of an appropriate carboxamide (0.25 mmol) dissolved in ethanol (3 mL) and NaOH (6 or 12 equiv) were sequentially added. The reaction mixture was heated at 80 °C for 12 h in an open atmosphere. Then, EtOH was removed under vacuum, and the reaction mixture was diluted with ethyl acetate (10-15 mL) and washed with aq. 1 N NaOH (5 mL x 2). The organic layer was concentrated under vacuum, and purification of the reaction mixture on a neutral alumina column furnished the

#### The Journal of Organic Chemistry

corresponding products **16a-e**. Then, the combined aqueous layers were acidified with 1 N HCl (15 mL x 2) to achieve a pH of  $\sim$ 2. The aqueous layers were extracted using ethyl acetate (10 mL x 2), and the combined organic layers were dried over anhydrous Na<sub>2</sub>SO<sub>4</sub> and evaporation under vacuum to afford the corresponding carboxylic acids **17a,b**.

*N*-(2-(Methylthio)phenyl)cyclopropanecarboxamide (1a):<sup>16g</sup> Following the general procedure, 1a was obtained after purification by column chromatography on neutral alumina (EtOAc:Hexanes = 5:95) as a colourless solid; mp 69-71 °C; Yield: 45% (93 mg); IR (KBr): 3264, 3005, 2916, 1651, 1578 cm<sup>-1</sup>; <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>):  $\delta$  8.53 (br. s,1H), 8.27 (d, 1H, *J* = 6.0 Hz), 7.44 (d, 1H, *J* = 7.7 Hz), 7.26-7.21 (m, 1H), 7.03 (t, 1H, *J* = 7.4 Hz), 2.36 (s, 3H), 1.63-1.58 (m, 1H), 1.10-1.06 (m, 2H), 0.87-0.82 (m, 2H); <sup>13</sup>C{<sup>1</sup>H} NMR (100 MHz, CDCl<sub>3</sub>):  $\delta$  172.0, 138.5, 132.7, 128.7, 125.2, 125.2, 124.2, 120.8, 18.9, 16.0, 8.2; HRMS (ESI): *m/z* [M + H]<sup>+</sup> calcd for C<sub>11</sub>H<sub>14</sub>NOS: 208.0796; found 208.0793.

*N*-(Quinolin-8-yl)cyclopropanecarboxamide (1b):<sup>16g</sup> Following the general procedure, 1b was obtained after purification by column chromatography on neutral alumina (EtOAc:Hexanes = 15:85) as a colourless solid; mp 81-83 °C; Yield: 83% (176 mg); IR (KBr): 3242, 3351, 1676, 1525, 1487 cm<sup>-1</sup>; <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>):  $\delta$  10.05 (br. s,1H), 8.83 (dd, 1H,  $J_1$  = 4.2 Hz,  $J_2$  = 1.6 Hz), 8.76 (dd, 1H,  $J_1$  = 7.3 Hz,  $J_2$  = 1.6 Hz), 8.18 (dd, 1H,  $J_1$  = 8.2 Hz,  $J_2$  = 1.6 Hz), 7.56-7.49 (m, 2H), 7.48 (dd, 1H,  $J_1$  = 8.2 Hz,  $J_2$  = 4.2 Hz), 1.87-1.81 (m, 1H), 1.20-1.16 (m, 2H), 0.96-0.91 (m, 2H); <sup>13</sup>C{<sup>1</sup>H} NMR (100 MHz, CDCl<sub>3</sub>):  $\delta$  172.3, 148.1, 138.2, 136.4, 134.7, 128.0, 127.5, 121.6, 121.2, 116.4, 16.3, 8.2; HRMS (ESI): m/z [M + H]<sup>+</sup> calcd for C<sub>13</sub>H<sub>13</sub>N<sub>2</sub>O: 213.1028; found 213.1035.

# ACKNOWLEDGMENTS

This work was funded by IISER-Mohali and partially by CSIR, New Delhi (Grant No. 02(0224)/15/EMR-II, Dt. 05-06-2015). We thank the central analytical facilities (NMR, HRMS and X-ray facilities) of IISER-Mohali and the single-crystal X-ray facility of the Department of

 Chemical Sciences, IISER-Mohali. B. G and S. M. thank DST, New Delhi for providing INSPIRE Fellowship and R. P. thanks CSIR, New Delhi, for providing SRF fellowship. We thank the Reviewers for giving valuable suggestions, which enabled us to clearly realize the proposed mechanism.

(17) For a selected paper dealing on the synthesis of  $\beta$ -acyloxy amides *via*  $\beta$ -acetoxylation of amides, see: (a) Zhou, L.; Lu, W.; *Org. Lett.* **2014**, *16*, 508. (b) For a selected recent paper dealing with retro-aldol reaction, see: Ganguly, B.; Kesharwani, M. K.; Matković, M.; Basarić, N.; Sing, A.; Mlinarić-Majerski, K. *J. Phy. Org. Chem.* **2011**, *24*, 578. (c) To support the proposed mechanism, we have recorded the crude NMR for the reaction mixture of the experiment involving amide hydrolysis of **5a** in the presence of K<sub>2</sub>CO<sub>3</sub>, which revealed the formation of *p*-tolualdehyde *via* the retro-aldol reaction (see the SI for the crude NMR). (d) Based on the literature reports regarding the ring opening reactions of cyclopropanes, during our revisiting of the C-H arylation of cyclopropanes we attained the C-H arylation/ring-opening of cyclopropanecarboxamides (e.g. **1a**), which successfully underwent with excess of aryl iodide in the presence of AcOH. Perhaps, in our previous work, Ref. 16g, we have missed the ring-opened product which is forming only in negligible quantity based on the optimization reaction Table 1. (e) A literature survey revealed that

in general, the removal of bidentate ligands, such as, 8-aminoquinoline and 2-(methylthio)aniline) was successful only under harsh reaction conditions (e.g., see Refs. 12 and 16a).

(18) Stereochemistry of the compounds 5a-l, 6a-e, 10, 11 and 12a-d: (a) The anti stereochemistry of the compounds 5a-l, 6a-e, 10, 11 and 12a-d was assigned based on the X-ray structures of the compounds **5b**, **6c**, **6d** and **12d** and the similarity in their NMR spectral pattern. (b) The respective reactions of 4a, 8, 15b with 2a-c and 2l are expected to give more than one isomer; however, the compounds 10, 11 and 12a-d were obtained as the predominant compounds from the column chromatography purification of the respective crude reaction mixtures and our trials to find out/obtain the formation of any other characterizable by-products were not fruitful. The structures of 10, 11 and 12a-d were assigned based on the retro-aldol reaction of 10, 11, and 12b,c, which afforded the corresponding compounds 16b,d,e (Scheme 3). Further the assignment of stereochemistry and structures of the compounds 10, 11 and 12a-e were supported by the singlecrystal X-ray structure of the compound 12d. Additionally, we have isolated the ring-opened carboxamide 23b (Scheme 6) from 13. Then, we have performed the Pd(OAc)<sub>2</sub>-catalyzed double C-H arylation reaction of the methyl group of 23b with 2c to afford the compound 12e. These sequences also supported the assigning of structures/stereochemistry of 10, 11 and 12a-d. (c) The reaction of 15a with iodobenzene also gave the product 5b (the NMR spectral pattern of 5b obtained in this reaction was similar to the product **5b** obtained from **1a**).

(20) (a) While the role of AgOAc is recognized that it helps in the ligand exchange step to regenerate the Pd(II) species (see Ref. 19); from the optimization reactions (Table 1) it is realized that the presence of AcOH perhaps eases the process of the C-H arylation/ring-opening of

#### The Journal of Organic Chemistry

cyclopropanecarboxamides in the presence of  $Pd(OAc)_2/AgOAc$ -catalytic system to afford the multiple C-H arylated aliphatic carboxamides 5/6/10-12 ( $\beta$ -acyloxy amides having *anti* stereochemistry). (b) It is noteworthy that typically, the C-H arylation/ring-opening of reactions of the cyclopropanecarboxamides **1a** (unsubstituted cyclopropanecarboxamide) or **9** (mono arylated cyclopropanecarboxamide) or **3b** (bis arylated cyclopropanecarboxamide) afforded the same product **5b**.

(21) (a) Ghosh, S.; Bhaumik, A.; Mondal, J.; Mallik, A.; Sengupta, S.; Mukhopadhyay, C. *Green. Chem.* 2012, *14*, 3220. (b) Tao, Y. T.; Saunders, W. H., Jr., *J. Am. Chem. Soc.* 1983, *105*, 3183.

(22) The *anti* stereochemistry of the compounds 21 and 22 was assigned based on their conversion into 5b and by comparing the NMR of 5b obtained from 21/22 as well as 1a. In analogy to these reactions, the stereochemistry of 23a was assigned. Similarly, the *anti* stereochemistry of the compounds 23b/12e was assigned based on the X-ray structure of 12d and the discussion given in Ref. 18.
