ARTICLE INFO

Keywords: Digitalis species Plantaginaceae cardenolide glycosides digigrandifloroside antiproliferative activity

ABSTRACT

Phytochemical investigation of the aerial parts of *Digitalis grandiflora* Miller (Plantaginaceae) led to the isolation of an undescribed cardenolide type glycoside digigrandifloroside (1) along with five known compounds, rengyoside A (2), rengyoside B (3), cleroindicin A (4), salidroside (5), and cornoside (6), from its aqueous fraction of methanolic extract. Structures of the isolated compounds were determined by means of spectroscopic techniques. **1–6** were isolated for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from *D. grandiflora*. **2** and **3** are being reported for the first time from a *Digitalis* species. Cytotoxic activity of the aqueous fraction was also tested against HEp-2 (Human larynx epidermoid carcinoma) and HepG2 (Human hepatocellular carcinoma) cancer cell lines and L929 (Mouse fibroblast cell) non-cancerous cell line. Aqueous fraction showed stronger cytotoxicity on HEp-2 cells than HepG2. Therefore, the cytotoxic activity of **1**, **2**, **4**, and **6** were tested against HEp-2 and L929 cell lines. **3** and **5** couldn't

1. Introduction

Plants have been used as folk medicines for a long time in history for the therapy of a wide range health problems. Evaluation of anticancer agents used in therapy, from 1940s to 2011, have shown that from 175 small molecular compounds approved 85 of them are natural products or derived from natural sources [23].

Although, there is no traditional use of genus *Digitalis* L., its first known use as a medicine was in 18th century by Withering. Nearly more than a half-century *Digitalis* species and *Digitalis*-derived cardioactive glycosides have been investigated for their effects in heart failure. Their toxicities and therapeutic effects were identified in detailed [18].

In the flora of Turkey, the genus *Digitalis* is presented by 9 species, 5 of which are endemic [5]. *Digitalis* species was formerly a member of Scrophulariaceae family, but after phylogenetic and chemotaxonomic studies it has been moved to Plantaginaceae. Cardioactive glycosides, phenylethanoid glycosides, flavonoids, and anthraquinones were reported from the genus *Digitalis* so far [16–18,27].

Cardioactive glycosides show their effect on myocardial cells by binding to Na-K ATPase pump to inhibit this ion transport enzyme [15]. Recent studies showed the role of cardioactive glycosides in cancer prevention and anticancer agents [22]. It was shown that Na-K ATPase pump α -1 subunit can play a role in proliferation and migration in cancer cells. The results of the study indicated that in cancer cells there became an over expression of α -1 subunit compared to normal cells. So, targeting this subunit could be an option in cancer therapy [22]. Some other reports also suggested different mechanisms for the cytotoxicity. Apoptosis, autophagy and immunologic cell death were also reported for cardioactive glycosides [30]. There are several reports about *in vitro* cytotoxic activity of cardioactive glycosides against different human cancer cell lines [27,28]. Fujino et al. [7] pointed out the selectivity between cancer cells and non-cancerous cells in their report. A cardioactive glycoside glucodigifucoside showed selective high cytotoxicity against ACHN (human renal adenocarcinoma cell line) when compared with HK-2 (normal human renal proximal tubule-derived cell line) [7].

Digitalis species also reported to have emetic, antibacterial, antiviral, antifungal, antiinflammatory and antioxidant activities [3,11,21,24,25,33].

The purpose of our study is the isolation of secondary metabolites with cytotoxic activity from the aerial part of *D. grandiflora*. *D. grandiflora* is an annual or perennial herb growing wildly in north-west

Turkey and Balkan region. There are only a few studies about the phytochemical content of the plant so far. Therefore, to clarify the chemical content, phytochemical studies were planned to perform. Bioactivity tests were also carried out according to the recent research interest on *Digitalis* species and cardenolide type glycosides. In this study, cytotoxicity was tested against both cancer (HEp-2, HepG2) and non-cancerous (L929) cell lines to determine the selectivity. This selectivity is important for the compounds to become an anticancer drug candidate.

2. Experimental

2.1. General experimental procedures

Optical rotations were recorded on a JASCO P-2100 polarimeter. HR-ESIMS data were obtained from Bruker Daltonics APEX III. ¹H-NMR (500 MHz), ¹³C-NMR (125 MHz) and 2D-NMR spectra of the compounds were measured in CD₃OD with an Agilent Varian VNS500 spectrometer. Chemical shifts (ppm) were referenced to the residual solvent peaks (δ_H 3.31 and δ_C 49.0). Tetramethylsilane was used as internal standard.

2.2. Chemicals/reagents and cell culture material

Column chromatography separations were carried out with polyamide (Polyamide 6, 50-160 µm; obtained from Sigma-Aldrich; St. Louis, MI, USA), silica gel (Kieselgel 60, 70–230 mesh, $0.063–0.2\,\mu m$, from Merck; Darmstadt, Germany) and RP silica gel (LiChroprep C18, 40-63 µm, Merck). D-glucose and L-rhamnose were obtained from Sigma-Aldrich. Lanatoside C was purchased from Fluka AG. TLC plates Silica gel 60 F₂₅₄, RP18 F₂₅₄ and all solvents were obtained from Merck. Etoposide was purchased from Deva Holding A.S. (Istanbul, Turkey). Fetal bovine serum (FBS), minimal essential medium with Earle's salts (MEM-Earle) and antibiotics (penicillin and streptomycin) were obtained from Biochrom AG (Berlin, Germany). Trypsin/EDTA solution was purchased from Merck. Dulbecco's Modified Eagle's Medium (DMEM), MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide] and sodium dodecyl sulphate was purchased from Sigma (St Louis, MI, USA). HEp-2 (Human larynx epidermoid carcinoma) cell line was obtained from Riken Bioresource Center Cell Bank (Tokyo, Japan). HepG2 (Human hepatocelular carcinoma) cells was obtained from Health Science Research Resources Bank (Osaka, Japan). L929 (Mouse fibroblast cell) cell line was purchased from Biota Lab (Istanbul, Turkey).

2.3. Plant material

Digitalis grandiflora Miller was collected from Kırklareli, Turkey in July, 2013. Identification of the plant was done by Dr. Z. Ceren Arituluk (Hacettepe University Faculty of Pharmacy Department of Pharmaceutical Botany, Ankara, Turkey). Voucher specimen was deposited in Hacettepe University Faculty of Pharmacy Herbarium (HUEF13007).

2.4. Extraction and isolation

Aerial parts of *D. grandiflora* was dried in appropriate conditions. Dried plant material was powdered, 290 g out of it was weighed and macerated in 5 L MeOH overnight, then extracted for 8 h at 40 °C. This procedure was repeated three more times. The extracts were combined and dried by evaporating under vacuum at 40 °C. The methanol extract was lyophilized to yield 37 g dry weight. The lyophilized extract was dissolved in 400 mL of water and partitioned with petroleum ether to discard lipophylic fractions. Aquoeus extracts (26 g) was used for cytotoxic activity tests and isolation studies.

The aquoeus extract (25 g) was subjected to polyamide column

chromatography and eluted with H_2O and continued by a gradient system with increasing ratios of MeOH from 25 to 100% MeOH to yield five different fractions (Fr. A, 21.3 g; Fr. B, 1.8 g; Fr. C, 0.50 g; Fr. D, 0.20 g; Fr. E, 0.10 g). Further chromatographic methods applied on Fr. A, which is the most cytotoxic fraction among the all fractions, to yield **1–6.** Fr.A was dissolved in H_2O and liquid-liquid extraction was performed using *n*-BuOH. 1 g of *n*-BuOH fraction (total 8.2 g) was subjected to silica gel column chromatography with a stepwise gradient system of CHCl₃: MeOH: H_2O (100:0:0–50:50:5). Isolation studies on subfractions yield to **1–6.**

1 and 5 were isolated from the silicagel column subfraction obtained by CHCl₃: MeOH: H_2O (75:25:2.5). Subfraction (65 mg) was applied to vacum liquid chromatography and eluted with MeOH: H_2O . 5 (6.5 mg) was eluted with 16% MeOH, 1 (9.4 mg) was eluted with 45% MeOH.

2 were isolated from the silicagel column subfraction obtained by CHCl₃: MeOH: H_2O (65:35:3.5). Subfraction (109 mg) was applied to vacum liquid chromatography and eluted with MeOH: H_2O . **2** (8.7 mg) was eluted with 8% MeOH.

3 and **6** were isolated from the silicagel column subfraction obtained by $CHCl_3$: MeOH: H_2O (70:30:3). Subfraction (140 mg) was applied to vacum liquid chromatography and eluted with MeOH: H_2O . Elution with 10% MeOH **3** (5.8 mg) and **6** (7 mg) were isolated.

4 was isolated from the silicagel column subfraction obtained by CHCl₃: MeOH: H_2O (80:20:2). Subfraction (169 mg) was applied to sephadex column chromatography and then applied to vacum liquid chromatography and eluted with MeOH: H_2O . **4** (99.2 mg) was eluted with 5% MeOH.

2.5. Cytotoxic activity

HEp-2, HepG2 and L929 cells were used for cytotoxic activity tests. Cells were seeded in a 96-well plate at a density of 1×10^5 cells/mL for HEp-2, 4×10^5 cells/mL for HepG2 and 8×10^4 cells/mL for L929 cells. MEM's Earle medium for HEp-2 and L929 cells and Dulbecco's Modified Eagle's Medium (DMEM) for HepG2 cell were used.

Cells were cultured in respective culture media supplemented with 10% FBS, 1% penicillin-streptomycin solution in a humidified 5% CO_2 in air at 37 °C for 24 h. Cells were treated with different concentrations of samples for the next 48 h. After incubation, the cells were washed and replaced by fresh medium. 10 μ L of MTT solution (5 mg/mL in PBS) was added and incubated for 4 h. After that, 100 μ L of 10% SDS (sodium dodecyl sulphate) was added to each well to dissolve formazan crystals. The absorbance was measured at 570/620 nm using microplate reader. Results were given as percentage of inhibitory effect treated cells to untreated cells that served as control [29]. Three independent test results were considered, averages and standard deviations were calculated and shown in the figures.

2.6. Statistical analysis

Results of MTT experiments are expressed as mean \pm standard deviation. The statistical significance was determined by one- way ANOVA post hoc Dunnett's test by using IBM SPSS Statistic 23 software. The IC₅₀ values were computed by GraphPad Prism 6.0 software (GraphPad Software Inc., San Diego, CA, USA).

2.7. Digigrandifloroside (1) (12-epidigoxigenin 3-O- β -D-glucopyranosyl (1 \rightarrow 4) β -D-digitoxopyranoside)

White amorphous powder; $[\alpha]_D^{22}$ + 7.0 (c 1.0, MeOH); ¹H and ¹³C NMR data, see Tables 1–3; HR-ESIMS: 705.34919 *m*/*z* [M + Na]⁺ (calculated for C₃₅H₅₄NaO₁₃ 705.34621).

 $^{1}\mathrm{H}$ (500 MHz) and $^{13}\mathrm{C}$ (125 MHz) NMR data and HMBC correlations of 1 in CD_3OD.

2.8. Acid hydrolysis and configuration determination of sugars

Compound 1 (2 mg) was dissolved in 1 mL of methanol and hydrolyzed with 2 mL of 12% HCl at 80 °C. The mixture was extracted with 2 mL of chloroform twice. The aqueous layer was dried under vacuum. Residue was dissolved in 100 μ L pyridine and 100 μ L of *N*-methyl-*N*-(trimethylsilyl) trifluoroacetamide (MSTFA) was added for derivatisation. D-glucose was used as sugar standard. D-digitoxose was obtained by hydrolyzation of the known compound lanatoside C. The same acid hydrolysis procedure was applied to lanatoside C. Sugar standards were also dissolved in 100 μ L pyridine and 100 μ L of MSTFA was added for silylation. Samples were analyzed by GC/MS analysis. Agilent 7890b Gas Chromatograph was used with HP-5 ms column (30 μ mx250 μ mx0.25 μ m). The injection volume was 1 μ L. Samples were applied to the column held initially at 40 °C for 1 min and then increased to 260 °C with a 15 °C/min heating ramp. The retention times

(min) of the derivatized sugar standards were as follows: D-glucose (14.23), D-digitoxose (13.59). D-glucose and D-digitoxose were detected in compound 1 by comparison with retention times of standard sugars.

3. Results and discussion

3.1. Structure elucidation of compounds

Isolation studies carried out on aqueous fraction of methanolic extract of *D. grandiflora* afforded 6 pure compounds (1–6), one of which was a new compound (1). Their chemical structures are shown in Fig. 1. 1, was obtained as a white amorphous powder, with the molecular formula C35H54O13 was established by HR-ESIMS m/z 705.34919 $[M + Na]^+$ in association with 35 carbon signals observed at ¹³C NMR data. The ¹³C NMR and DEPT spectra revealed 35 carbon signals including three methyl ($\delta_{\rm C}$ 17.7, 18.6, 24.2; CH₃), eleven methylene ($\delta_{\rm C}$ 22.5, 27.5, 27.8, 30.2, 30.3, 31.0, 31.3, 35.0, 39.1, 62.3, 75.7; CH₂), sixteen methine (δ_{C} 30.2, 38.0, 42.8, 46.7, 68.6, 69.6, 71.1, 74.5, 75.1, 76.5, 77.7, 77.9, 84.3, 96.8, 105.8, 117.7; CH), and five quaternary ($\delta_{\rm C}$ 36.0, 54.6, 86.6, 177.3, 179.6; C) carbons (Table 1). The detailed examination of HR-ESI-mass (MS), ¹H, ¹³C, COSY, HMQC, HMBC, and NOESY NMR spectra suggested this substance should be a cardenolide type glycoside. All ¹H and ¹³C NMR data and HMBC correlations were given in Table 1. ¹H NMR signals of α,β -unsaturated γ -lactone [δ 4.98] (1H, brd, J = 18.5 Hz, H-21b), 4.94 (1H, brd, J = 18.5 Hz, H-21a) oxymethylene signals, and 5.90 (1H, brs, H-22) olefinic signal] have been seen at ¹H NMR spectrum. At ¹³C NMR spectrum the signals corresponding to these protons [δ 117.7, CH, (C-22) and 75.7, CH₂, (C-21)] with C signals [δ 177.3, CO, (C-23) and 179.6 C, (C-20)] supported the presence of a lactone ring in the structure. Two methyl signals at δ 0.83 (3H, s, H-18) and δ 0.94 (3H, s, H-19) and an oxygen bearing quaternary carbon (δ 86.6, C-14) was determined. Signals of methyl and methylene protons between $\delta_{\rm H}$ 1.30–2.30 ppm were evaluated together with the data given above. Oxymethylene signals at $\delta_{\rm H}$ 4.02 (brs, H-3) and 3.59 (brs, H-12) ppm were also detected. The ¹³C signals corresponding to these protons were determined using HMQC spectra. Fragments were generated by means of ¹H-¹H COSY spectrum and they were coupled up by using long range correlations observed in HMBC spectrum. According to these findings, the aglycone of 1 was considered to possess similar chemical structure with digoxigenin. Therefore, ¹H and ¹³C NMR spectral data was compared with the data of digoxigenin [9,20,26] and it was recognized that the data of 1 showed discrepancy

^a Signal patterns are unclear due to overlapping.

from the literature. The $^{13}\mathrm{C}$ signal belongs to C-18 methyl group (δ 17.7, CH₃) at C-13 of 1 shifted downfield approximately 8 ppm and signal of C-13 (δ 54.6, C) shifted downfield approx. 3 ppm [20,26] (Table 1). The relative configuration of these groups was clarified by the correlations observed in the NOESY spectrum. The key NOESY correlations were shown in Fig. 2. The NOESY correlations were observed between H-12 with H-18 in the spectrum. In addition, there was no correlation observed between H-17 and H-18. These findings suggested that the C-12 hydroxyl group should be attached to the skeleton in α configuration which differs from digoxigenin. The ¹³C NMR data of 12- α hydroxyl and 12- β hydroxyl digoxigenin given in the literature were compared with the data of compound 1 [9]. The chemical shifts observed for C and D rings confirmed that hydroxyl group at C-12 is in α configuration. ¹³C NMR spectra was compared with the literature data and A/B and C/D connections were found as *cis* and B/C was *trans*. With all the data mentioned above showed that aglycone was a 12 epimer of digoxigenin.

Anomeric proton signals at δ 4.92 (H, brd, J = 8.0 Hz, H-1') and 4.38 (H, d, J = 8.0 Hz, H-1") at ¹H NMR spectrum indicated the presence of a sugar moiety with two sugar unites. The coupling constants of these anomeric signals explained that both sugar units are in β configuration. The signals: a methyl group at δ 1.30 (3H, d, J = 6.5 Hz, H-6'); seven oxymethines at δ 3.23 (H, dd, J = 8.0, 8.0 Hz, H-2"), 3.28 (H, m, H-4'), 3.28 (H, m, H-5"), 3.34 (H, m, H-3"), 3.34 (H, m, H-4"), 3.87 (H, m, H-5'), 4.30 (H, ddd, J = 3.0, 3.0, 3.0 Hz, H-3'); a methylene at δ 1.74 (H, m, H-2'a) and 1.95 (H, m, H-2'b), an oxymethylene at δ 3.70 (H, dd, J = 12.0, 5.0 Hz, H-6"a) and 3.82 (H, dd, J = 12.0, 2.0 Hz, H-6"b). The sugar moiety was deduced as digitoxose and glucose using ¹H-¹H COSY spectrum and carbon signals were identified using HMQC correlations. The signals at δ_H 1.74–1.95 ppm (H-2') and δ_H 1.30 ppm (3H, d, J = 6.5 Hz, H-6') showed the 2,6 dideoxyose structure of digitoxose as the first sugar. The long range correlations observed between H-1" of glucose ($\delta_{\rm H}$ 4.38, d) and C-4' of digitoxose ($\delta_{\rm C}$ 84.3) in the HMBC spectrum indicated that the second sugar unite was attached at the 4th position of the first sugar unite (Fig. 3, Table 1). Combining the HMBC and COSY spectra the sugar moiety was identified as β - glucopyranosil $(1 \rightarrow 4) \beta$ - digitoxopyranoside. HMBC correlation between H-1' and C-3, and the occurrence of H-3 oxymethine signal at δ 4.02 as a

broad singlet explained that the sugar unit connected to the aglycone at C-3 in β -orientation. Configuration of the sugars were determined as D-glucose and D-digitoxose by GC/MS analysis. Therefore, the structure of **1** was determined to be 12-epidigoxigenin 3-O- β -D-glucopyranosyl $(1 \rightarrow 4) \beta$ -D-digitoxopyranoside and named as digigrandifloroside. There is no literature data that the presence of 12-epidigoxigenin as a naturally occuring aglycone in the cardenolide type glycosides so far. Synthetic derivatives of 12-epidigoxigenin were reported in the literature [9]. Therefore, we have suggested this unusual aglycone was isolated from nature for the first time with this study.

The known compounds were characterized as rengyoside A (2), rengyoside B (3) [31], cleroindicin A (4) [32], salidroside (5) and cornoside (6) [19] comparing their NMR and physical data with published data in the literature. ¹H and ¹³C NMR data of the known compounds were given in Tables 2 and 3. Rengyosides A and B are being reported for the first time from *Digitalis* species and Plantaginaceae family with this study. This is the second report for the isolation of cleroindicin A from *Digitalis* species, the first report was from *D. trojana* [17].

3.2. Cytotoxic activity

The aqueous fraction of *D. grandiflora* methanolic extract was tested for its cytotoxicity against Hep-2, HepG2 cancer cells and L929 noncancerous cells. Extract showed higher cytotoxicity with an IC_{50} value of 63.7 µg/mL on Hep2 cells when compared to HepG2 cells with an IC_{50} value of 514 µg/mL (Table 4). This difference showed that the extract has selectivity between cancer cell lines. Therefore, Hep2 cells were selected for the cytotoxicity tests of the isolated compounds. Cytotoxic activity of the extract was found to be lower on L929 cell line with an IC_{50} value of 215 µg/mL (Table 4). The selectivity was also observed between cancer and non-cancerous cell lines.

Digigrandifloroside (1), rengyoside A (2), cleroindicin A (4), and cornoside (6) were evaluated for their cytotoxic activity against HEp-2 cancer cell line and L929 noncancerous cell line. Etoposide was used as positive control as it is a semisynthetic derivative of a nature originated compound, podophyllotoxin. IC_{50} values for rengyoside A (2), cleroindicin A (4) and cornoside (6) on HEp-2 cell line were found to be

Fig. 1. Structures of the isolated compounds from D. grandiflora

382, 2.56×10^3 , $2.03 \times 10^3 \,\mu\text{M}$ respectively. These compounds showed concentration dependent low cytotoxicity against selected cancer cell line. Their cytotoxicity on L929 cells were almost two folds lower than they had on HEp-2 cells. IC₅₀ values for rengyoside A (2) and cornoside (6) on L929 cell line were found to be 1.20×10^3 and $3.77 \times 10^3 \,\mu\text{M}$, respectively (Table 4).

The new compound digigrandifloroside (1) showed concentration dependent high cytotoxicity against HEp-2 cells which is significant when compared with the positive control etoposide (Fig. 4, Table 4).

Digigrandifloroside has an IC_{50} value of $10.1 \,\mu$ M on HEp-2 cells and IC_{50} value of $12.9 \,\mu$ M on L929 cells (Table 4). In comparison with an anticancer agent etoposide, digigrandifloroside showed higher potential on HEp-2 cell line. In previous reports cardenolide type glycosides were tested on several cell lines. Digoxin was tested against brain SH-SY5Y, brain SK-N-AS, breast MDA-MB-231, breast MDA-MB-435, liver Hep3B, prostate PC3, prostate PPC-1, and transformed human B-lymphocytes P493-Myc cancer cells [4]. SH-SY5Y and SK-N-AS neuroblastoma cell lines were found to be the most sensitive among the tested

Fig. 2. The key NOESY correlations of compound 1

Fig. 3. The key HMBC correlations of compound 1

 Table 4

 IC₅₀ values of extract and compounds against HEp-2, HepG2 and L929 cell lines

Extract/Compounds	IC ₅₀ values					
	Cell lines					
	Hep-2	HepG2	L929

Cleroindicin A (4) Cornoside (6) Etoposide	$2.56 \times 10^{3} \mu M$ $2.03 \times 10^{3} \mu M$ $39.5 \mu M$	nd. ^a nd. ^a nd ^a	2.58 × 10 ³ μM 3.77 × 10 ³ μM 45.2 μM			

^a Not determined.

cell lines with the IC_{50} values of 34 and 22 ng/mL. The clinical studies performed on digoxin at prostate cancer is in Phase II level [1]. Lanatoside C was tested against U87 glioblastoma cells and the IC_{50} value was calculated as $1\,\mu g/mL$ [2].

Even there is no other study reported on HEp-2 cancer cells treated with cardenolide glycoside so far, digigrandifloroside showed lower cytotoxicity than digoxin and some other cardenolide glycosides against cancer cells. In this study, IC_{50} of digigrandifloroside was found as $10.1 \,\mu$ M corresponding to $6.9 \,\mu$ g/mL. The epimerisation at C-12 position could be responsible from the lower cytotoxic activity of digigrandifloroside when compared with other cardenolide glycosides.

When the cytotoxicity results evaluated in detailed, it could be seen that digigrandifloroside showed biphasic effect, both cytotoxic and cytostatic (antiproliferative), depends on concentration, on L929 cell line (Figs. 5 and 6). A dramatical decrease in cell viability (cytotoxic effect) observed till $5\,\mu g/mL$ concentration corresponding to $7.33\,\mu M$ (cell viability; 52.51%). Cytostatic (antiproliferative) effect was observed with the increase of digigrandifloroside concentration. Even at 100 and 200 μ g/mL concentrations corresonding to 146 and 293 μ M of digigrandifloroside, viability of L929 cells were found as 41.0 and 36.4% respectively (Fig. 5). However, the viability % of HEp-2 cells at 100 and 200 $\mu g/mL$ concentrations corresponding to 146 and 293 μM of digigrandifloroside, were found as 1.23 and 1.09% respectively (Fig. 4). These results showed that the cytostatic activity can't be seen on Hep-2 cells, as high cytotoxicity have been detected. Although the IC₅₀ values of digigrandifloroside were found to be similar on Hep-2 and L929 cells, it has a type of activity selectivity between cancer and noncancerous cells (Fig. 6).

4. Conclusion

Studies on aqueous fraction of methanolic extract of *D. grandiflora* afforded 1 new total 6 compounds. All compounds were isolated for the first time from *D. grandiflora*. Among the isolated compounds, rengyosides A (2) and B (3) were reported in *Digitalis* genus and

Fig. 4. Screening cytotoxic activity of digigrandifloroside and etoposide on HEp-2 cell line using MTT method. Results are given as inhibition %, and expressed as mean \pm S.D. (n = 3). *p < 0.05 as compared to positive control etoposide.

Fig. 5. Screening cytotoxic activity of digigrandifloroside and etoposide on L929 cell line using MTT method. Results are given as inhibition %, and expressed as mean \pm S.D. (n = 3). *p < 0.05 as compared to positive control etoposide.

Plantaginaceae family for the first time. In previous studies, rengyoside A was isolated only from Oleaceae (*Forsythia* sp.) and Bignoniacae (*Millingtonia* sp.) families, and rengyoside B was isolated from Oleaceae (*Forsythia* sp.), Bignoniacae (*Incarvillea, Markhamia, Millingtonia, Santisukia, Tecoma* sp.) and Lamiaceae (*Clerodendrum* sp.) families [8,10,12–14,31,34]. This is the second time for cleroindicin A (4) being reported from *Digitalis* species, the first report was from *D. trojana* [17]. Previous studies on rengyoside A and B showed that these structures can be afforded by biogenesis like transformation starting from salidroside [6]. Salidroside firstly transform to cornoside, and then rengyosides A and B occur respectively. While salidroside is distributed widely in different plant families, the distribution of rengyosides A and B is restricted. In the future studies, this type of compounds with cleroindicin structure might be studied in detailed with the view of chemotaxonomy of the related families.

Structure of a new cardenolide glycoside named digigrandifloroside (1) has been identified by advanced spectral analysis. Cytotoxic activity tests performed on the extract and the isolated compounds. Digigrandifloroside showed strong cytotoxicity on Hep-2 cancer cell line with the IC_{50} value of $10.1 \,\mu$ M when compared with anticancer agent etoposide used as a positive control. Digigrandifloroside also showed selectivity between cancer and noncancerous cell lines. The antiproliferative (cytostatic) effect was seen against noncancerous cells. This selectivity is valuable for the future studies to evaluate the structure activity relationship of the epimerisation in C-12 of the cardenolide glycosides.
