### Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

# Boronic Acid–Appended Molecular Glues for ATP-Responsive Activity Modulation of Enzymes

**ABSTRACT:** Water-soluble linear polymers  $\text{Gu}_m\text{BA}_n$  ( $m/n = 18/6, 12/12, \text{ and } 6/18$ ) with multiple guanidinium ion ( $\text{Gu}^+$ ) and boronic acid (BA) pendants in their side chains were synthesized as ATP-responsive modulators for enzyme activity.  $\text{Gu}_m\text{BA}_n$  polymers strongly bind to the phosphate ion ( $\text{PO}_4^-$ ) and 1,2-diol units of ATP via the  $\text{Gu}^+$  and BA pendants, respectively. As only the  $\text{Gu}^+$  pendants can be used for proteins,  $\text{Gu}_m\text{BA}_n$  is able to modulate the activity of enzymes in response to ATP. As a proof-of-concept study, we demonstrated that trypsin (Trp) can be deactivated by hybridization with  $\text{Gu}_m\text{BA}_n$ . However, upon addition of ATP, Trp was liberated to retrieve its hydrolytic activity due to a higher preference of  $\text{Gu}_m\text{BA}_n$  toward ATP than Trp. This event occurred in a much lower range of  $[\text{ATP}]$  than reported examples. Under cellular conditions, the hydrolytic activity of Trp was likewise modulated.

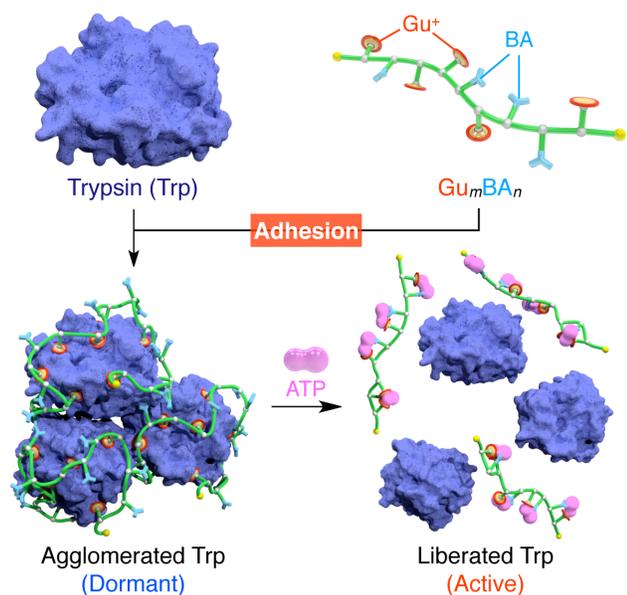

Chemicals that act site-selectively in tumor tissue are attractive for tumor chemotherapy and drug delivery. Tumor targeting is mostly based on a difference in pH between the tumor (pH 5.9–7.6) and normal tissue (pH 7.3–8.0).<sup>1,2</sup> Adenosine triphosphate (ATP; Figure 1b) represents a promising tumor indicator, as the concentration of extracellular ATP in tumor tissue ( $[\text{ATP}] > 100 \mu\text{M}$ )<sup>3</sup> is more than four orders of magnitude higher than that in normal tissue ( $[\text{ATP}] = 1\text{--}10 \text{ nM}$ ).<sup>4</sup> Previously, a few examples of ATP-responsive drug delivery carriers using DNA aptamers<sup>5</sup> and phenylboronic acid<sup>6</sup> have been reported. However, these systems were designed to distinguish extracellular and intracellular matrices, and operate at  $[\text{ATP}] > 1 \text{ mM}$ . Recently, we reported an ATP-responsive drug carrier, consisting of tubularly connected chaperon units, which can operate at  $[\text{ATP}] = 10\text{--}50 \mu\text{M}$ , albeit that the system requires esterase to cleave off a drug linker for the release of encapsulated drugs.<sup>7</sup> Here we report a series of water-soluble polymers,  $\text{Gu}_m\text{BA}_n$ , as ATP-responsive molecular glues that carry mul-

multiple guanidinium ion ( $\text{Gu}^+$ ) and boronic acid (BA) pendants in their side chains (Figure 1a).  $\text{Gu}_m\text{BA}_n$  polymers can temporarily suppress the activity of an enzyme by hybridization (Figure 2). However, upon addition of ATP, the enzyme is liberated and can retrieve its intrinsic activity. Most importantly, this event occurs in a much lower range of  $[\text{ATP}]$  (1–10  $\mu\text{M}$ ) than previous examples including our chaperon nanotubes.<sup>5–7</sup>

Previously, we developed dendritic<sup>8a–8c</sup> and linear<sup>8f–8i</sup> mo-

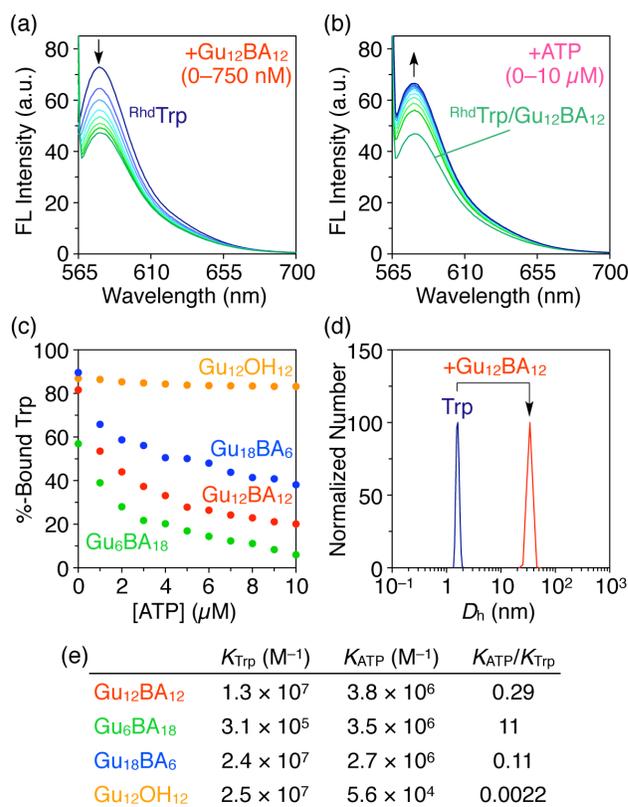

**Figure 1.** (a) Molecular glues  $\text{Gu}_m\text{BA}_n$  ( $m/n = 18/6, 12/12, \text{ and } 6/18$ ) with randomly incorporated guanidinium ion ( $\text{Gu}^+$ ) and boronic acid (BA) moieties in their side chains, as well as of  $\text{Gu}_m\text{OH}_n$  ( $m/n = 12/12$ ) without BA units; (b) adenosine triphosphate (ATP); (c) schematic illustration of (left) a salt-bridge between phosphate ion ( $\text{PO}_4^-$ ) and  $\text{Gu}^+$ , and (right) covalent bonds between 1,2-diol and BA moieties.

**Figure 2.** Schematic illustration of the modulation of the enzymatic activity of trypsin (Trp) by  $\text{Gu}_m\text{BA}_n$  and ATP.  $\text{Gu}_m\text{BA}_n$  adheres to the surface of Trp to form agglomerates and thus suppresses Trp enzymatic activity (dormant state). ATP competitively binds to  $\text{Gu}_m\text{BA}_n$ , which allows its dissociation from Trp, thus restoring the enzymatic activity.

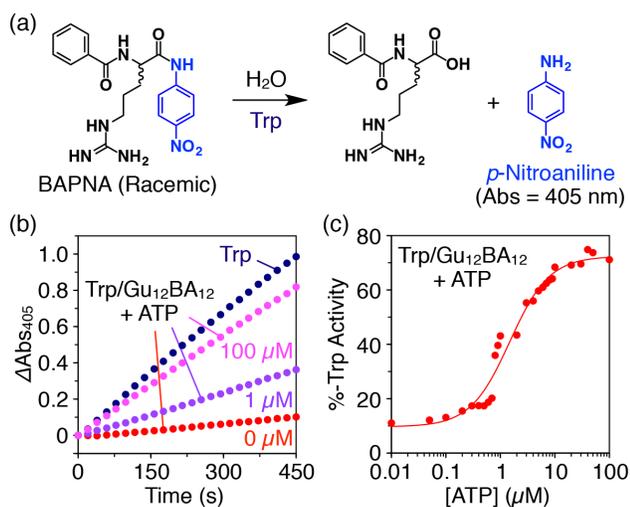

lecular glues containing multiple  $\text{Gu}^+$  units.<sup>9</sup> These molecular glues strongly adhere to proteins,<sup>8a,8c,8e,8g</sup> nucleic acids,<sup>8h,8i</sup> phospholipid membranes,<sup>8d</sup> and clay nanosheets<sup>8b,8f</sup> via multiple salt bridges between  $\text{Gu}^+$  and oxyanionic groups<sup>9</sup> located on the targets.  $\text{Gu}_m\text{BA}_n$  (Figure 1a) were designed as a new class of molecular glues containing not only  $\text{Gu}^+$  but also BA units that can covalently bind to 1,2-diols (Figure 1c).<sup>10</sup> The cooperative effect of multiple  $\text{Gu}^+/\text{PO}_4^-$  salt bridges and covalently bound BA/1,2-diol moieties (Figure 1c) should result in a high affinity of  $\text{Gu}_m\text{BA}_n$  toward ATP (Figure 1b), which may be able to liberate proteins from their  $\text{Gu}_m\text{BA}_n$  conjugates (Figure 2). As a proof-of-concept study, we chose a hydrolytic enzyme trypsin (Trp) as a target protein. Trp is known to inhibit the proliferation and metastasis of cancer cells,<sup>11</sup> and thus may possibly exhibit tumor-suppressing activity. However, Trp is not tissue selective and thus also deteriorates normal tissue.<sup>11</sup> Here we highlight that the hydrolytic activity of Trp, which is intrinsically independent of ATP, can be modulated via conjugation with  $\text{Gu}_m\text{BA}_n$ , and that this conjugation is essentially reversible upon addition of ATP (Figure 2).

$\text{Gu}_m\text{BA}_n$  polymers (Figure 1a) were synthesized using the “thiol-yne” reaction<sup>12</sup> between alkyne-appended monomers containing  $\text{Gu}^+$  and BA units, and a triethylene glycol with thiol termini. With different molar ratios of two alkyne-appended monomers,  $\text{Gu}_{18}\text{BA}_6$ ,  $\text{Gu}_{12}\text{BA}_{12}$ , and  $\text{Gu}_6\text{BA}_{18}$  were synthesized. The oxidation of  $\text{Gu}_{12}\text{BA}_{12}$  with  $\text{H}_2\text{O}_2$  furnished  $\text{Gu}_{12}\text{OH}_{12}$  as a reference, which contains hydroxyl (OH) groups instead of BA units (Figure 1a). The average molecular weights of  $\text{Gu}_m\text{BA}_n$  and  $\text{Gu}_m\text{OH}_n$  were evaluated

**Figure 3.** Fluorescence spectra ( $\lambda_{\text{ext}} = 560$  nm) of sulforhodamine B-labeled Trp ( $\text{RhdTrp}$ ,  $0.5 \mu\text{M}$ ) at  $25^\circ\text{C}$  in Tris-HCl buffer (20 mM, pH 7.8) upon successive titration with (a)  $\text{Gu}_{12}\text{BA}_{12}$  (0–750 nM) and (b) ATP (0–10  $\mu\text{M}$ ). (c) Dissociation profiles of  $\text{Gu}_{12}\text{B}_{12}$  (red; 750 nM),  $\text{Gu}_{18}\text{BA}_6$  (blue; 800 nM),  $\text{Gu}_6\text{BA}_{18}$  (green; 4.5  $\mu\text{M}$ ), and  $\text{Gu}_{12}\text{OH}_{12}$  (orange; 700 nM) from  $\text{RhdTrp}$  ( $0.5 \mu\text{M}$ ) at  $25^\circ\text{C}$  in Tris-HCl buffer. Fractions of bound Trp were calculated from the fluorescence intensity at 578 nm. (d) DLS histograms of Trp ( $0.5 \mu\text{M}$ ) in the absence (dark blue) and presence (red) of  $\text{Gu}_{12}\text{BA}_{12}$  (700 nM) at  $25^\circ\text{C}$  in Tris-HCl buffer. (e) Association constants of  $\text{Gu}_{12}\text{B}_{12}$ ,  $\text{Gu}_{18}\text{BA}_6$ ,  $\text{Gu}_6\text{BA}_{18}$ , and  $\text{Gu}_{12}\text{OH}_{12}$  toward Trp ( $K_{\text{Trp}}$ ) and ATP ( $K_{\text{ATP}}$ ) determined according to the reported methods.<sup>15,16</sup>

by quantification of the thiol termini (Table S1).<sup>13</sup> Subsequently, we labeled Trp with a fluorescence probe sulforhodamine B ( $\text{RhdTrp}$ ,  $0.5 \mu\text{M}$ ) and conducted titration experiments with  $\text{Gu}_{12}\text{BA}_{12}$  (0–750 nM) in Tris-HCl buffer (20 mM, pH 7.8) at  $25^\circ\text{C}$ , as the adhesion of  $\text{Gu}_{12}\text{BA}_{12}$  to  $\text{RhdTrp}$  quenches the fluorescence emission at 578 nm ( $\lambda_{\text{ext}} = 560$  nm; Figure 3a).<sup>14</sup> According to an established method,<sup>15</sup> we fitted the fluorescence intensity changes to a 1:1 binding model, and obtained an association constant ( $K_{\text{Trp}}$ ) of  $1.3 \times 10^7 \text{ M}^{-1}$  for the binding between  $\text{Gu}_{12}\text{BA}_{12}$  and Trp (Figure 3e). A similar fluorescence-quenching profile was observed for  $\text{RhdTrp}$  with  $\text{Gu}_{18}\text{BA}_6$  ( $K_{\text{Trp}} = 2.4 \times 10^7 \text{ M}^{-1}$ ; Figures 3e and S12a),<sup>13</sup> as well as  $\text{Gu}_{12}\text{OH}_{12}$  ( $K_{\text{Trp}} = 2.5 \times 10^7 \text{ M}^{-1}$ ; Figures 3e and S12e).<sup>13</sup> In contrast,  $\text{Gu}_6\text{BA}_{18}$  barely quenched the fluorescence (Figure S12c),<sup>13</sup> and a much smaller  $K_{\text{Trp}}$  value ( $3.1 \times 10^5 \text{ M}^{-1}$ ; Figure 3e) relative to that of  $\text{Gu}_{12}\text{BA}_{12}$  was observed, indicating that the binding to Trp occurs pre-

**Figure 4.** (a) Schematic representation of Trp-catalyzed hydrolysis of BAPNA to *p*-nitroaniline. (b) Absorption changes at 405 nm of Trp (0.5  $\mu\text{M}$ , dark blue), as well as of a mixture of Trp,  $\text{Gu}_{12}\text{BA}_{12}$  (10  $\mu\text{M}$ ), and ATP (0, 1, and 100  $\mu\text{M}$ ; red, purple, and pink, respectively) in Tris-HCl buffer (50 mM, pH 7.8) containing BAPNA (1 mM) and  $\text{CaCl}_2$  (10 mM) at 37  $^\circ\text{C}$ . (c) Normalized enzymatic activity of Trp (0.5  $\mu\text{M}$ ) in the presence of  $\text{Gu}_{12}\text{BA}_{12}$  (10  $\mu\text{M}$ ) and ATP (0.01–100  $\mu\text{M}$ ).

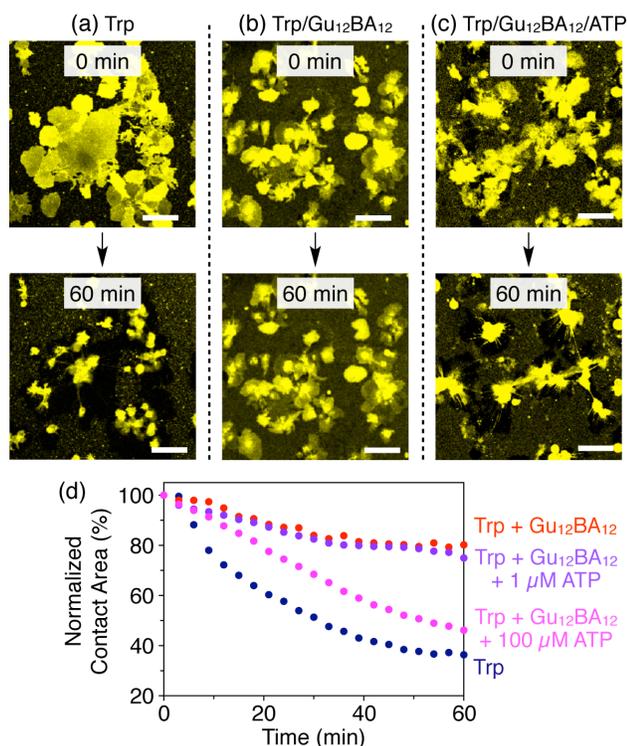

dominantly via  $\text{Gu}^+$ . Dynamic light scattering (DLS) measurements revealed that  $\text{Gu}_{12}\text{BA}_{12}$  (700 nM) adheres to Trp (0.5  $\mu\text{M}$ ; Figure 3d, dark blue) to yield agglomerates with an average diameter of  $\sim 70$  nm (Figure 3d, red).<sup>8g</sup>

Subsequently,  $\text{Gu}_m\text{BA}_n$  that adheres to Trp can be detached by addition of ATP. For example, when ATP (0–10  $\mu\text{M}$ ) was added to a conjugate of  $\text{Rh}^{\text{d}}\text{Trp}$  (0.5  $\mu\text{M}$ ) and  $\text{Gu}_{12}\text{BA}_{12}$  (750 nM; Figure 3a), the fluorescence emission at 578 nm increased as expected (Figure 3b). The fraction of  $\text{Gu}_{12}\text{BA}_{12}$ -bound  $\text{Rh}^{\text{d}}\text{Trp}$  decreased nonlinearly as a function of [ATP] (Figure 3c, red), as evaluated from the change of the fluorescence profile using the extinction coefficient of  $\text{Gu}_{12}\text{BA}_{12}$  for  $\text{Rh}^{\text{d}}\text{Trp}$ .<sup>15</sup> For example, when 10  $\mu\text{M}$  of ATP was added, the %-fraction of  $\text{Gu}_{12}\text{BA}_{12}$ -bound  $\text{Rh}^{\text{d}}\text{Trp}$  dropped from 80% to 20% (Figure 3c, red). An association constant for  $\text{Gu}_{12}\text{BA}_{12}$  toward ATP ( $K_{\text{ATP}}$ ) of  $3.8 \times 10^6 \text{ M}^{-1}$  (Figure 3e) was obtained by fitting the dissociation profile (Figure 3c, red) to the competitive binding model.<sup>16</sup> Likewise,  $K_{\text{ATP}}$  values for  $\text{Gu}_6\text{BA}_{18}$  ( $3.5 \times 10^6 \text{ M}^{-1}$ ; Figure 3c, green) and  $\text{Gu}_{18}\text{BA}_6$  ( $2.7 \times 10^6 \text{ M}^{-1}$ ; Figure 3c, blue) were determined (Figure 3e). Although the  $K_{\text{Trp}}$  of  $\text{Gu}_{12}\text{OH}_{12}$  is comparable to that of  $\text{Gu}_{12}\text{BA}_{12}$ , ATP was virtually unable to liberate Trp from  $\text{Gu}_{12}\text{OH}_{12}$  (Figure 3c, orange). For  $\text{Gu}_{12}\text{OH}_{12}$ , a much smaller  $K_{\text{ATP}}$  value ( $5.6 \times 10^4 \text{ M}^{-1}$ ; Figure 3e) relative to that of  $\text{Gu}_{12}\text{BA}_{12}$  was observed, which highlights the crucial role of the BA units in the ATP-responsive nature of  $\text{Gu}_m\text{BA}_n$ . The binding of  $\text{Gu}_m\text{BA}_n$  to ATP strongly depends on multivalent  $\text{Gu}^+/\text{PO}_4^-$  salt-bridge interactions. In fact, toward AMP, an ATP analogue with only one  $\text{PO}_4^-$  unit, the association constant for  $\text{Gu}_{12}\text{BA}_{12}$  ( $K_{\text{AMP}}$ :  $8.7 \times 10^2 \text{ M}^{-1}$ ; Figure S14)<sup>13</sup> was 4,400-fold smaller than the corre-

sponding  $K_{\text{ATP}}$ . The relative affinity toward ATP and Trp ( $K_{\text{ATP}}/K_{\text{Trp}}$ ; Figure 3e) can be tuned via the  $\text{Gu}^+/\text{BA}$  ratio. Among the examined  $\text{Gu}_m\text{BA}_n$  polymers,  $\text{Gu}_6\text{BA}_{18}$  exhibited the highest  $K_{\text{ATP}}/K_{\text{Trp}}$  ratio (11; Figure 3e) due to its small  $K_{\text{Trp}}$  value. Although  $\text{Gu}_{12}\text{BA}_{12}$  exhibited  $K_{\text{ATP}}/K_{\text{Trp}} < 1$ , it was used for the following studies on account of its high  $K_{\text{ATP}}$  and  $K_{\text{Trp}}$  values (Figure 3e). In principle, BA/1,2-diol binding is pH-sensitive.<sup>10</sup> However, judging from the binding behavior to Alizarin Red S, a fluorescent diol (Figure S12),<sup>13</sup> the BA units of  $\text{Gu}_{12}\text{BA}_{12}$  could certainly bind to the 1,2-diol unit of ATP also at a typical pH (6.8) of tumor tissue.

We then examined the ATP-responsive enzymatic activity of Trp. Upon mixing *N*- $\alpha$ -benzoyl-DL-arginine 4-nitroanilide (BAPNA, 1 mM) with Trp (0.5  $\mu\text{M}$ ) at 37  $^\circ\text{C}$  in Tris-HCl buffer (50 mM, pH 7.8) containing  $\text{CaCl}_2$  (10 mM), the characteristic absorption at 405 nm increased (Figure 4b, dark blue), indicating that BAPNA was hydrolyzed to *p*-nitroaniline (Figure 4a).<sup>17</sup> Conversely, BAPNA was hydrolyzed only very sluggishly (Figure 4b, red) when  $\text{Gu}_{12}\text{BA}_{12}$  (10  $\mu\text{M}$ ) was used under otherwise identical conditions. This result might be ascribed to the agglomeration of Trp (Figure 3d), which would lower the accessibility of the active site of Trp. However, the hydrolysis, which was suppressed by  $\text{Gu}_{12}\text{BA}_{12}$ , could be accelerated by addition of ATP (1 and 100  $\mu\text{M}$ ; Figure 4b, purple and pink, respectively). When  $\text{Gu}_m\text{BA}_n$  was absent, the hydrolytic activity of Trp remained intact to the addition of ATP (Figure S17).<sup>13</sup> The hydrolytic activity of Trp in the presence of  $\text{Gu}_{12}\text{BA}_{12}$  and ATP was evaluated by using pseudo-first order reaction kinetics, and normalized relative to that of untreated Trp. A sigmoidal correlation was observed between the %-activity of Trp and [ATP] (Figure 4c), which resulted in an abrupt increase in hydrolytic activity of Trp upon increasing [ATP] from 1  $\mu\text{M}$  to 10  $\mu\text{M}$ . Considering the concentrations of ATP in tumor and normal tissues (*vide supra*), this threshold is favorable for tumor targeting.

Then, we attempted to extend this strategy to cellular systems. Trp can be used to detach cells from a culture substrate by degrading cell surface components involved in the adhesion to the substrate. Therefore, we immersed human hepatocellular carcinoma Hep3B cells, fluorescently labelled with CellBrite Orange,<sup>13</sup> in a Hank's balanced salt solution (HBSS, pH 7.8) containing Trp (5  $\mu\text{M}$ ), before we subjected the sample to confocal laser scanning microscopy ( $\lambda_{\text{ext}} = 552 \text{ nm}$ ). As shown in Figure 5a, the cells were detached from the substrate. Accordingly, the cell/substrate contact area, calculated from the fluorescence micrographs by using the ImageJ software, decreased over a period of 60 min (Figure 5d, dark blue).<sup>18</sup> In sharp contrast, Hep3B cells barely detached (Figures 5b and 5d, red) when they were treated with a mixture of Trp (5  $\mu\text{M}$ ) and  $\text{Gu}_{12}\text{BA}_{12}$  (10  $\mu\text{M}$ ) under otherwise identical conditions, thus indicating the suppression of enzymatic activity of Trp. Subsequently, we added 100  $\mu\text{M}$  of ATP to the system, whereupon the cells started to

**Figure 5.** Confocal laser scanning micrographs ( $\lambda_{\text{exc}} = 552 \text{ nm}$ ; 0–60 min) of Hep3B cells ( $5.0 \times 10^3$  cells/chamber) fluorescently labelled with CellBrite Orange in HBSS (pH 7.8) containing Trp ( $5 \mu\text{M}$ ) at  $25^\circ\text{C}$ . Micrographs recorded in the absence (a) and presence of (b)  $\text{Gu}_{12}\text{BA}_{12}$  ( $10 \mu\text{M}$ ) or (c) both  $\text{Gu}_{12}\text{BA}_{12}$  ( $10 \mu\text{M}$ ) and ATP ( $100 \mu\text{M}$ ). Scale bars =  $100 \mu\text{m}$ . (d) Normalized contact areas between Hep3B cells and the substrate in HBSS containing Trp ( $5 \mu\text{M}$ ) at  $25^\circ\text{C}$  in the absence (dark blue) and presence of  $\text{Gu}_{12}\text{BA}_{12}$  ( $10 \mu\text{M}$ , red), as well as in the presence of both  $\text{Gu}_{12}\text{BA}_{12}$  and ATP ( $1$  or  $100 \mu\text{M}$ , purple and pink, respectively); calculated from the micrographs using the ImageJ software.

detach efficiently, even in the presence of  $\text{Gu}_{12}\text{BA}_{12}$  (Figures 5c and 5d, pink). It is noteworthy that  $1 \mu\text{M}$  of ATP hardly affected the cell detachment rate (Figure 5d, purple). These results suggest that  $\text{Gu}_{12}\text{BA}_{12}$  remains bound to Trp in an ordinary cellular environment, but liberates Trp in ATP-rich areas such as tumor tissue.

In conclusion, we developed novel molecular glues,  $\text{Gu}_m\text{BA}_n$ , carrying multiple guanidinium ion ( $\text{Gu}^+$ ) and boronic acid (BA) pendants, as ATP-responsive modulators for the activities of enzymes.  $\text{Gu}_m\text{BA}_n$  binds tightly to ATP as well as to proteins. The enzymatic activity of trypsin (Trp) was effectively modulated *in vitro* and in cellular systems using  $\text{Gu}_m\text{BA}_n$  and ATP. As Trp/ $\text{Gu}_m\text{BA}_n$  conjugates may potentially be sensitive to ATP-rich ( $>100 \mu\text{M}$ ) tumor tissue, *in vivo* pharmacological studies may furnish interesting results.
