Scheme A

yield of the corresponding isopropylidene derivative^{3,4}, β -diketones or β -keto esters fail to yield this product. We have, therefore, investigated the conversion of a series of enolates ions 2 to the α -alkylidene derivates 4 via the S_{RN} 1 process (Scheme B).

Scheme B

The conversion of 1 ($R^1 = C_6H_5$, $R^2 = OC_2H_5$) to 4a using 2-chloro-2-nitropropane (3, $R^3 = CH_3$) with a variety of base/solvent systems using a 1:1:1 molar ratio of 1:3: base and sunlamp irradiation was studied. Irradiation is not required, but the reaction occurs more rapidly with irradiation. Even with irradiation, the reactions are completely inhibited by the presence of 5 mol% of di-t-butyl nitroxide as expected for the chain process of Scheme A. Best results were obtained with sodium hydride/dimethyl-formamide (50% yield of 4a after 20 h). Other systems studied include: lithium diisopropylamide/tetrahydrofuran (no reaction after 8 h), sodium hydride/dimethyl sulfoxide (39% yield in 8 h), potassium hydride/dimethyl sulfoxide (42% yield in 21 h), and potassium t-butoxide/3:1 t-butanol/dimethyl sulfoxide (35% yield in 20 h).

The sodium hydride/dimethylformamide system was chosen as the most convenient and further experiments were conducted with a 2-fold excess of the enolate 2 as shown in Scheme B (see Table 1).

Three of the products were obtained as keto-enol mixtures (4c, 4e, and 4f), which were analyzed by 'H-N.M.R. spectrometry (the keto and enol tautomers of 3-isopropylidene-2,4-pentane-dione (4f) have been previously reported)⁵. In the case of the

 α -Alkylidene Derivatives of β -Diketones and β -Keto Esters; 2-Chloro-2-nitropropane as an Acetone Equivalent in Controlled Cross-Aldol-Type Processes

Glen A. RUSSELL*, Boguslaw MUDRYK, Mikolaj JAWDOSIUK Department of Chemistry, Iowa State University, Ames, Iowa, 50011, U.S.A.

Geminal halo-nitro-alkanes will participate in the $S_{RN}1$ process (Scheme A) with enolate anions of cycloalkanones or ω -alkylacetophenones to yield β -nitro-ketones which readily eliminate nitrous acid to yield α,β -unsaturated ketones².

The reactions are sensitive to the nature of the counterion and solvents used to prepare the enolate anion. Although diethyl malonate and acetone can be condensed to give a moderate

two α -cyclohexylidene derivatives (Scheme C), two keto forms and one enol form were readily distinguished by ¹H-N.M.R. spectrometry⁶.

Scheme C

The utility of α -halonitroalkanes as ketone equivalents is increased by their facile synthesis from ketoximes by chlorination in dichloromethane followed by oxidation with nitric acid in cyclohexane in overall yields of 70%.

Ethyl α -Isopropylideneacetoacetate (4b); Typical Procedure:

In a 100 ml flask equipped with a thermometer, dropping funnel, rubber septum for hypodermic injection, and a nitrogen purge, there is placed

[&]quot; Reaction in the dark.

sodium hydride (1.20 g, 0.05 mol) and dimethylformamide (30 ml). The solution is stirred by a magnetic stirrer while ethyl acetoacetate (2; $R^1 = CH_3$, $R^2 = OC_2H_5$; 6.5 g, 0.05 mol) is added dropwise over a 1 h period followed by an additional 3 h to insure complete conversion to the enolate anion. 2-Chloro-2-nitropropane (3; $R^3 = CH_3$; 2.7 ml, 0.025 mol) is injected from a syringe and the solution stirred for 3 h approximately 6 in from a 275 Watt sunlamp which maintains a reaction temperature of 35 °C. The reaction product is poured into water (200 ml), and the organic products are extracted with hexane (30 ml) followed by benzene (3 × 25 ml). The combined extracts are washed with 5% aqueous sodium hydroxide (75 ml) and dried with magnesium sulfate. Vacuum distillation gives 4b; yield: 3.25 g (77%); b.p. 100-102 °C/6 torr.

Table 2 lists the properties of the α -alkylidene derivatives and gives references to previous indirect syntheses.
