S Supporting Information

ABSTRACT: The chemistry of a palladium(II) complex containing both an alkyl– and an aryl–palladium bond is reported. The reaction of $[Pd(CH_2CMe_2C_6H_4)(MesN=CHCH=NMes)]$ with bromine or iodine leads to reductive elimination of 1,1-dimethylcyclobutabenzene with formation of $[PdX_2(MesN=CHCH=NMes)]$ (X = Br, I). However, the reaction with hydrogen peroxide gives $[Pd-(CH_2CMe_2C_6H_4O)(MesN=CHCH=NMes)]$ by overall oxygen atom insertion into the aryl–palladium rather than the alkyl–palladium bond. This complex $[Pd-(CH_2CMe_2C_6H_4O)(MesN=CHCH=NMes)]$ reacts with bromine, iodine, or hydrogen peroxide to give 3,3-dimethyl-2,3-dihydrobenzofuran and the corresponding complex

 $[PdX_2(MesN=CHCH=NMes)]$. The mechanisms of reaction and basis for selectivity are discussed. The results support the view that oxygen atom insertion is a mechanistically viable pathway for selective catalytic oxidation of hydrocarbons by the green oxidant hydrogen peroxide.

INTRODUCTION

The development of organopalladium(IV) chemistry in recent years has been impressive and has stimulated research into catalysis involving Pd(II)/Pd(IV) cycles to complement the many important catalytic reactions involving Pd(0)/Pd(II) cycles.^{1,2} The higher oxidation state catalysis has the greatest potential in reactions carried out under oxidizing conditions, including the functionalization of hydrocarbons to form oxygenated or halogenated derivatives.¹⁻³ These catalytic reactions typically contain steps involving oxidation of palladium(II) to palladium(IV) by oxygen, halogen, or their equivalents (i.e., peroxide or hypervalent halide oxidants), followed by reductive elimination involving C–O or C–X (X = halogen) bond formation. It is therefore important to understand the factors that influence reactivity and selectivity in these reactions.¹⁻³

Palladium(IV) complexes containing both Pd–C(sp³) and Pd–C(sp²) bonds, such as *A* (Scheme 1), allow a direct study of selectivity in reductive elimination.^{4–6} The Sanford group has shown that the first step in the reductive elimination from *A* is dissociation of the ligand X^- (e.g., $X^- = PhO^-$, NO_3^- , OTs^- , NHTs⁻) to give the 16-electron 5-coordinate intermediate *B*. This Pd(IV) intermediate can undergo reduction to Pd(II) through three possible routes: (1) nucleophilic attack by $X^$ gives *C* with CH₂–X bond formation, (2) concerted intramolecular reductive elimination with CH₂–F bond formation gives *D*, or (3) reductive elimination of C–C gives 1,1dimethylcyclobutabenzene and *E*. The 14-electron complexes *D* and *E* undergo further coordination with X⁻ to give squareplanar 16-electron palladium(II) complexes. The selectivity in Scheme 1. Competition among C-X (X = OR, NHR), C-F, and C-C Reductive Elimination from the Palladium(IV) Complex A^4

the reductive elimination is dependent on the nature of the anion $X^{-,4}$

The Mirica group showed that the palladium(II) complex F (Scheme 2) was easily oxidized by oxygen or hydrogen peroxide to give the stable hydroxopalladium(IV) complex G, from which, on heating to 110 °C in dimethyl sulfoxide solution, reductive elimination occurred to give a complex that

Received: May 12, 2016

Scheme 2. Reductive Elimination with Selective Aryl C–O Bond Formation⁵

was formulated as H.⁵ In contrast to the Sanford complexes of Scheme 1,⁴ the reductive elimination from G involves selective $C(sp^2)-O$ rather than $C(sp^3)-O$ bond formation, probably by a concerted intramolecular mechanism.⁵ The tentatively assigned intermediate H subsequently reacts with acid to give 2-*tert*-butylphenol. Protonolysis of a metal–carbon bond in the related compound $[Pd(CH_2CMe_2C_6H_4)(PMe_3)_2]$ with phosphine instead of amine donor ligands is proposed to occur through a transient hydridopalladium(IV) intermediate and can lead to cleavage of either the Pd– $C(sp^3)$ or Pd– $C(sp^2)$ bond, though the latter is favored kinetically.^{6a}

These observations show that the nature of the supporting ligands play a key role in controlling the selectivity of sp^2 or sp^3 C–X bond formation. The Me₃TACN and hydroxo ligands in *G* (Scheme 2) do not easily dissociate; therefore, reaction is proposed to occur directly from the 6-coordinate 18-electron complex.⁵ However, the X⁻ ligand in *A* (Scheme 1), which is trans to a high trans influence alkyl group, dissociates reversibly and, as has been established for several related palladium(IV) and platinum(IV) complexes,^{1,7} the reductive elimination occurs more easily from the 16-electron intermediate *B*.⁴

The commonly acknowledged pathways for reductive C–O bond formation include a stepwise nucleophilic attack (i.e., Scheme 1) or a concerted pathway. A third, less well studied pathway involves overall oxygen atom insertion into a Pd–C bond. Hillhouse found that treatment of the nickel(II) complex *I* with nitrous oxide afforded a Ni(II) dimer *J* with an oxygen atom inserted selectively into the Ni–C(sp²) bond (Scheme 3).⁸ Oxidation of the monomer *K* with iodine leads to formation of the diiodonickel(II) complex *L* and the benzofuran derivative BF, through C(sp³)–O reductive elimination.

Oxygen atom insertion into arylpalladium or arylrhodium bonds has also been established in complexes where no alkylpalladium bond is present (Scheme 4). Several oxygen

^{*a*}Reagents: (i) MCPBA, C_6F_5IO , or $H_2O_2/Fe(III)$ catalyst; (ii) *t*-BuOOH/[V(O)(acac)₂] catalyst.

atom donors could be used but, in most cases, oxidation with hydrogen peroxide or *tert*-butyl hydroperoxide required an iron(III) or vanadium(IV) catalyst (Scheme 4).⁹ The mechanism was proposed to involve a transient oxopalladium-(IV) intermediate, whose possible nature has recently been probed theoretically.¹⁰ Only with ligand assistance has the direct reaction with hydrogen peroxide in water been observed (Scheme 5).^{3a}

Recently, the hydroxylation of arenes using O_2 or H_2O_2 as the environmentally benign oxidant and O atom source has been achieved, with some examples using palladium(II) catalysts.¹¹ The identification of the operative pathway for C–O bond formation is critical for the continued optimization of catalytic functionalization of both arenes and alkanes.¹⁻³ Herein, we study the reactions of the palladium(II) complex $[Pd(CH_2CMe_2C_6H_4)(MesN=CHCH=NMes)]$ with the oxidants H_2O_2 and halogens. We chose the diimine ligand MesN=CHCH=NMes¹² on the basis that the nitrogen donors will allow oxidation to the Pd(IV) state (compare Schemes 1 and 2),^{4,5} while the steric bulk of the N-mesityl substituents will promote reductive elimination. The reactions lead to C-O and C-C bond formation from the palladacycle, including selective oxygen atom insertion from the hydrogen peroxide oxidant.

RESULTS AND DISCUSSION

The complex $[Pd(CH_2CMe_2C_6H_4)(MesN=CHCH=NMes)]$ (1) was prepared by ligand exchange from the corresponding 1,5-cyclooctadiene complex $[Pd-(CH_2CMe_2C_6H_4)(COD)]^{5,6}$ and MesN=CHCH=NMes¹² according to eq 1. The best yield of 75% was obtained by

carrying out the reaction in ether solution at -65 °C for 17 h. Once obtained in pure form, complex 1 was thermally stable and could be stored at room temperature in air for extended periods. In order to facilitate subsequent reaction monitoring of 1, a complete assignment of the ¹H and ¹³C NMR spectra of the complex was made by using a combination of correlated ¹H–¹H COSY and ¹H–¹³C HSQC and HMBC NMR spectra. Complex 1 has effective C_s symmetry, and its ¹H NMR spectrum contained two singlet imine resonances at δ 7.06 and 7.05 and two sets of mesityl resonances. The CH₂ and CMe₂ resonances of the hydrocarbon ligand appeared at δ 2.48 and 1.49, respectively.

The structure of complex 1 was determined and is shown in Figure 1. Along with a molecule of ether, there are two

Figure 1. Structures of the two independent molecules of complex 1, showing 30% probability ellipsoids. Selected bond distances (Å) and angles (deg): Pd(1)C(1A) 1.994(4); Pd(1)C(8A) 2.018(4); Pd(1)-N(1A) 2.170(3); Pd(1)N(2A) 2.119(3) Å; C(1A)Pd(1)C(8A) 79.42(16); N(2A)Pd(1)N(1A) 76.82(12)°; Pd(2)C(1B) 1.993(4); Pd(2)C(8B) 2.039(5); Pd(2)N(2B) 2.117(3); Pd(2)N(1B) 2.158(3); C(1B)Pd(2)C(8B) 79.43(18); N(2B)Pd(2)N(1B) 76.57(13).

independent but similar molecules of 1 found in the unit cell, designated by Pd(1) and Pd(2). Both molecules are square planar with very small values of Houser's τ_4 parameter of 0.053 and 0.042 ($\tau_4 = 0$ for an ideal square-planar complex).¹³ A significant difference between the two molecules is in the degree of nonplanarity of the metallacycle formed with the hydrocarbon ligand. In the Pd(2) molecule C(6B) and C(7B) are displaced out of the square plane by 0.33 and 0.77 Å, respectively. In Pd(1), a higher degree of distortion by 0.10 Å is observed for both C(6A) and C(7A). A difference in the twist

angles of the mesityl groups with respect to the square plane of the palladium center is also observed between Pd(1) and Pd(2). The angle between the square plane and the two mesityl planes are 77 and 91° for the Pd(1) molecule and 79 and 78° for the Pd(2) molecule.

The reaction of complex 1 with bromine or iodine occurred largely according to eq 2 to give 1,1-dimethylcyclobutabenzene

(CB) and the corresponding palladium(II) complex [PdX₂(MesN=CHCH=NMes)] (**2a**, X = Br; **2b**, X = I). The 1,1-dimethylcyclobutabenzene, which was characterized by its ¹H NMR and mass spectra,^{4b,14} is presumed to be formed by reductive elimination, with C–C bond formation, from a palladium(IV) intermediate by analogy with the mechanism of Scheme 1.⁴ However, when the reaction was monitored by ¹H NMR spectroscopy, no palladium(IV) complex was detected; therefore, this presumed intermediate is transient. The complexes **2a**,**b** have effective $C_{2\nu}$ symmetry, and in contrast to **1**, the ¹H NMR spectra contained only one imine resonance and one set of mesityl resonances. The structures of **2a**,**b** were determined and are shown in Figure 2. Both structures are

Figure 2. Structures of complexes 2a (left) and 2b (right), with ellipsoids shown at the 50% probability level. Selected bond distances (Å) and angles (deg) for 2a: Pd(1)N(1) 2.023(3); Pd(1)Br(1) 2.4085(5); N(1)Pd(1)N(1A) 79.92(14); Br(1)Pd(1)Br(1) 93.47(3). Selected bond distances (Å) and angles (deg) for 2b: Pd(1)N(1A) 2.065(2); Pd(1)N(2A) 2.069(2); Pd(1)I(2A) 2.5668(5); Pd(1)I(1A) 2.5700(5); N(1A)Pd(1)N(2A) 79.03(9); I(2A)Pd(1)I(1A) 90.437(17).

square planar (τ_4 : 2a, 0.00; 2b, 0.079). In the structure of 2a the molecule contains a crystallographic 2-fold rotation axis. The structure of 2b is more complex, and the repeat unit has the formula (2b)₃·2(acetone), with three independent but similar molecules of 2b, only the Pd(1) molecule of which is shown in Figure 2.

The reaction of complex 1 with hydrogen peroxide occurred, with selectivity different from the reactions with halogens, according to eq 3. The reaction to give the product

 $\left[Pd(CH_2CMe_2C_6H_4O)(MesN=CHCH=NMes) \right] \end{tabular} (3) occurs by selective oxygen atom insertion into the aryl-palladium bond. The product is analogous to that observed previously by Hillhouse⁸ on oxidation of Ni(II) complexes with N_2O (Scheme 3). To identify the optimal reaction conditions, the conversion was monitored by ¹H NMR spectroscopy by following the diagnostic imine singlets of 1 and 3 (Table 1 and$

^{*a*}All reactions were carried out under air and at room temperature (see the Experimental Section for details). ^{*b*}Dielectric constant of solvent. ^{*c*}The yield of **3** was calculated by integration of its imine resonances relative to the internal standard 1,3,5-trimethoxybenzene.

Figure 3. ¹H NMR spectra in the region of the imine protons during reaction of complex 1 with 2 equiv of H_2O_2 in $(CD_3)_2CO$ at room temperature to give complex 3. Spectra depict (a) authentic 1 and the reaction mixture of 1 and H_2O_2 after (b) 10 min, (c) 2 h, and (d) 3 h.

Figure 3). The conversion to 3 is highest in more polar solvents (Table 1, entries 1–4), suggesting a charge-separated species is important in the formation of 3. Alternatively, the more polar solvent may promote miscibility of the H_2O_2 solution (30% in H_2O). Using acetone as the optimal solvent, the reaction time was increased from 1 to 3 h, giving a maximum conversion of 82% (entry 5). The formation of 3 is thus considerably slower than reaction of 1 with the halogens to give 2a,b (eq 2), in which a dramatic color change is observed within minutes. Different amounts of H_2O_2 in the range of 1–4 equiv were

tested (entries 5–9), revealing that 2 equiv is optimal. The decrease in observed yield of 3 with greater amounts is notable in the context of catalytic applications, where an oxidant is used in considerable excess to the catalyst. Here, the low conversion with greater amounts is, at least in part, due to subsequent reactivity of 3 to release the organic ligand as a benzofuran product (vide infra). The optimization reveals that the maximum conversion to 3 (82%) is achieved in acetone with 2 equiv of H₂O₂ in a reaction time of 3 h, and the isolated yield was 50% under these conditions.

Compound 3 was fully characterized by ¹H and ¹³C NMR and IR spectroscopy, mass spectrometry, elemental analysis, and X-ray crystallography. The ¹H NMR spectrum gives two sets of imine and mesityl resonances, indicating that 3 has C_s symmetry (Figure 3). The singlet resonances for CH₂ and CMe₂ are found at δ 1.73 and 1.10, respectively, upfield of those found for **1**.

The structure of complex 3 was determined as the benzene solvate and is shown in Figure 4. The structure confirms the

Figure 4. View of the structure of complex 3 (ellipsoids at 50% probability). Cocrystallized benzene and hydrogen atoms are not shown, for clarity. Selected bond distances (Å) and angles (deg): Pd(1)O(1) 1.9900(10); Pd(1)C(1) 2.0124(12); Pd(1)N(2) 2.0187(11); Pd(1)N(1) 2.1685(10); O(1)Pd(1)C(1) 92.45(4); N(2)Pd(1)N(1) 78.12(4).

selectivity for O atom insertion is for the Pd– $C(sp^2)$ bond. The six-membered PdC₄O ring adopts a twist-chair conformation, with the atom C(6) having the highest displacement of 0.64 Å from the palladium square plane. The two mesityl rings are twisted out of the square plane of the palladium diimine ring by 67 and 79°.

The complex **3** reacted with bromine or iodine oxidants to give the corresponding complex **2a** or **2b** and 3,3-dimethyl-2,3-dihydrobenzofuran (BF) according to eq 4. Complexes **2a,b**

were characterized as described above, while the organic product 3,3-dimethyl-2,3-dihydrobenzofuran was identified by its NMR and mass spectra and isolated in 27% yield from the reaction with iodine.¹⁵ The reaction is expected to occur by an oxidative addition-reductive elimination sequence, but no palladium(IV) intermediate was detected. The presumed reductive elimination step occurs selectively by $C(sp^3)-O$ bond formation, rather than $C(sp^3)-X$ bond formation. The formation of 2a,b and BF is consistent with halide oxidation of the analogous O atom inserted nickel complex studied by Hillhouse⁸ (Scheme 3). The reaction of 1 with excess hydrogen peroxide occurs to give 3 (eq 3), and then further reaction occurs with release of 3,3-dimethyl-2,3-dihydrobenzofuran (eq 4). In this case the expected dihydroxopalladium(II) complex 2c has not been obtained in pure form. When the reaction with H_2O_2 was monitored by ¹H NMR spectroscopy, imine resonances for a symmetrical complex, suggested to be 2c, were observed but they decayed over a period of hours. It is well-known that hydroxopalladium(II) complexes tend to form dimers or oligomers by forming bridging hydroxide or oxide groups, and this may occur with the proposed complex 2c.^{16,17} However, we have not been able to isolate pure products or to identify them by NMR spectroscopy or ESI-MS or MALDI-MS, and the characterization of 2c remains tentative. The requirement for excess hydrogen peroxide in this case suggests that a parallel palladium-catalyzed decomposition of hydrogen peroxide may occur.¹

A solution of complex 3 in acetone- d_6 reacted quickly with CO (1 atm) to give a precipitate of palladium black. After 15 min, the solution was filtered to remove the Pd and the organic products were identified as the free diimine ligand and 4,4-dimethyl-2-oxo-2*H*-1-benzopyran (BP) by their ¹H NMR spectra (eq 5). The formation of the benzopyran derivative

BP was confirmed by GC-MS and was the only product derived from the palladacycle unit of **3** that was detected. In this case, the product is suggested to form by CO insertion followed by reductive elimination from a palladium(II) complex intermediate. The nickel(II) complex J (Scheme 3) gives a similar reaction with carbon monoxide to form BP.⁸

To gain more insight into the selective oxygen atom insertion reaction to give complex 3, DFT calculations were carried out (see the Experimental Section for details). Some of the potential reactions of complex 1 with hydrogen peroxide are shown in Scheme 6, and calculations of the energies of reaction were carried out for each case. The simplest reactions considered were trans or cis oxidative addition to give the palladium(IV) complexes 5a-c. More complex reactions involve oxidative addition followed by either reductive elimination with C-O bond formation to give 3 or 4 and water or 6 or 7 or reductive elimination with C-C bond formation to give 2c and 1,1-dimethylcyclobutabenzene (CB). Of the palladium(IV) isomers 5a-c, the product of trans oxidative addition, 5a, is calculated to be most stable and, in related platinum(II) chemistry, trans oxidative addition is also preferred kinetically in the polar mechanism of oxidative addition of O-O bonds.¹⁸ Formation of complex 3 or 4

Scheme 6. Potential Reactions of Complex 1 with H_2O_2 and Calculated Energies of Reaction (kJ mol⁻¹)

involves overall oxygen atom insertion into the $Pd-C(sp^2)$ or $Pd-C(sp^3)$ bond, respectively, and formation of 3 is favored by 45 kJ mol⁻¹ over 4. Similarly, the complex 6 or 7 would be formed by formal $C(sp^2)$ -O or $C(sp^3)$ -O reductive elimination from 5a-c. Product 6 (which is analogous to complex H in Scheme 2) is calculated to be at lower energy than 7 by 45 kJ mol⁻¹. The theory thus indicates that the products of aryl-oxygen bond formation, 3 and 6, which are related by addition or loss of water, are thermodynamically most stable. Simple calculated bond energies favor 6 over 3 + H_2O by 9 kJ mol⁻¹, but if the water remains hydrogen bonded to 3, then $3 \cdot H_2O$ is more stable than 6 by 41 kJ mol⁻¹. Of course, entropy effects favor $3 + H_2O$ over 6. The products will, of course, be controlled by kinetic factors, but the selective formation of complex 3 (Scheme 6) is consistent with there being a lower activation energy for formation of a more stable product.

A suggested mechanism of reaction to give complex 3 is shown in Figure 5. The initial encounter complex 8 is formed between complex 1 and H_2O_2 involving donation from the filled $4d_{z^2}$ orbital of 1 to the vacant $\sigma^*(OO)$ orbital of H₂O₂, indicated by M in Figure 5, leading to an increase in the calculated O-O bond distance from 1.59 to 1.72 Å. The ratedetermining step is likely to involve further charge transfer to H_2O_2 with cleavage of the O-O bond to give the proposed palladium(IV) complex intermediate 9. Complex 9 can be considered to contain a Pd⁺OH group hydrogen bonded to hydroxide or an oxopalladium (Pd⁺O⁻) group hydrogen bonded to water. The importance of such an intermediate is consistent with the experimental observation that polar solvents are preferable for this reaction. Since the reagent used was 30% aqueous H₂O₂, it is likely that additional water molecules may be involved in stabilizing 9, and so its structure is tentative. With this proviso, the calculation suggests that it should be

Figure 5. Calculated structures and relative energies (kJ mol⁻¹) of complexes and intermediates in the reaction of **1** with H_2O_2 to give complex **3**. *I* represents the proposed initial interaction between the $4d_2^2$ HOMO of complex **1** and the σ^* LUMO of H_2O_2 . Selected calculated bond parameters (distance in Å and angles in deg): H_2O_2 , O–O 1.59, O–H 1.01; **6**, Pd···O 2.47, O–O 1.72, PdO–H 1.00, PdOO–H 1.01, Pd···O–O 177; 7, Pd–O 1.98, O···O 2.57, PdO···H 1.54, PdOH–O 1.05, PdOHO–H 1.00; **8**, Pd–O 2.02, O···O 2.77, PdO···H 1.77, PdOH–O 1.01, PdOHO–H 0.99; **3**, Pd–O 2.02.

considered primarily as an oxo complex, with the significant hydrogen bonding to water (Figure 5) providing a mechanism to avoid the "oxo wall".^{10,20} Once C–O bond formation begins, the formation of complex 10, which is just complex 3 hydrogen bonded to water, is very favorable, and then dissociation of water gives the observed product 3. The mechanism (Figure 5) can be considered to combine the deprotonation and bond formation steps of the proposed Mirica mechanism⁵ of Scheme 2. Generation of 3 via the latter, stepwise path cannot be conclusively discarded. In such a process, complex 10 could be considered to be an intermediate on the way to a phenol derivative along with hydroxide, and this step could be followed by deprotonation of the phenol to give 3. Deprotonation would be disfavored in the Mirica system, since such a step would generate the strong acid $HClO_4$ rather than the 1 equiv of H_2O_4 produced here.

Scheme 7 shows the potential products and their relative energies from reaction of complex 1 with bromine and iodine. In this case the reaction to give 2a and 1,1-dimethylcyclobutabenzene (CB) is calculated to be most favorable, again consistent with the experimental observations. The preference for C–C over C–X reductive elimination is calculated to follow the sequence X = I > Br > OH (Schemes 6 and 7) and can be rationalized by the relative Pd–X and C–X bond dissociation energies, with D(C-X) - D(Pd-X) following the ligand hardness sequence X = OH > Br > I. In contrast to the case with X = OH (Scheme 6), the theory predicts that, for C–X bond formation, reaction at C(sp³) is preferred over that at C(sp²), with 11 being lower in energy than 12 (Scheme 7).

Scheme 7. Possible Products and Their Relative Energies (kJ mol⁻¹) from Reaction of Complex 1 with Bromine or Iodine

In the above examples, the thermodynamically more stable products are also favored kinetically, as they are the experimentally observed products. This is also the case for the reactions of 3 with Br_2 and I_2 (Scheme 8). The calculations

show that oxidation followed by intramolecular $C(sp^3)-O$ reductive elimination to give BF and **2a,b** is more favorable than reductive elimination to give **15a,b** that contains a new $C(sp^3)-X$ bond (X = Br, I). In contrast, **2c** and BF are not the most favorable products for oxidation of **3** with H₂O₂. Instead, the more stable product is expected to be **15c** or the cyclic derivative **16**. Experimentally BF is observed as a product of oxidation of **3** with H₂O₂ (eq 4). It is expected that the products in all of the reactions are determined by kinetic control and this is the only case in which the product is not also the most thermodynamically stable, as calculated by DFT.

From a mechanistic point of view, the reductive elimination following oxidation of 3 with Br_2 , I_2 , or H_2O_2 is likely to occur from a five-coordinate Pd(IV) intermediate (Scheme 9 for the representative example with I_2). Initial attack by the electro-

Scheme 9. Likely Mechanism for Reactions of Complex 3 with Oxidants X_2 (X = Br, I, OH) and the Relative Energies (kJ mol⁻¹) for the Case with X = I

philic iodine is likely to give the diiodine complex 12, for which several precedents are known.²¹ Complete I–I bond cleavage from 12 followed by attack of the iodide ion at palladium or at the CH₂ group would give 9b or 10b, respectively (Scheme 8). However, intramolecular C–O reductive elimination to give 2b is evidently preferred, perhaps after pseudorotation of 12 to give the isomer 13 so that the initial benzofuran (BF) palladium(II) complex 15 is formed in its most stable form by way of transition state 14. Then displacement of BF by iodide via complex 16 completes the reaction.

CONCLUSIONS

The initial reaction of complex 1 with hydrogen peroxide occurs to give selective oxygen atom insertion into the arylpalladium bond to give complex 3 (eq 3), while the reactions with bromine and iodine lead to intramolecular C-C bond formation to give 1,1-dimethylcyclobutabenzene and 2a or 2b (eq 2). Complex 3 reacts with all three oxidants by intramolecular C-O bond formation to give 3,3-dimethyl-2,3dihydrobenzofuran and 2a, 2b, or 2c (eq 4). In most cases, experimentally observed oxidation products were calculated to be the most thermodynamically stable products. This suggests that, in similar systems, thermodynamic stability can act as a good guide for kinetically controlled oxidation selectivity. The observed oxygen atom insertion may be an operative process in C–O bond forming reactions catalyzed by Pd with H_2O_2 as the oxidant. The selectivity observed here is promising for a greater development in catalytic oxidations of hydrocarbons.

EXPERIMENTAL SECTION

Reagents and General Procedures. All reactions were carried out in air, unless otherwise specified. For those reactions that were conducted under a nitrogen atmosphere, standard Schlenk techniques were used. All solvents used for air- and moisture-sensitive reactions were purified using an Innovative Technologies 400-5 Solvent Purification System (SPS) and were stored over activated 4 Å molecular sieves. NMR spectra were recorded at 298 K using Varian INOVA 400 and 600 MHz spectrometers. ¹H and ¹³C chemical shifts were referenced internally to solvent (residual signal for ¹H) where the chemical shift was set to appropriate values relative to TMS at 0.00 ppm. Complete assignments of each compound were aided by the use of ¹H–¹H gCOSY, ¹H–¹³C{¹H} HSQC, and ¹H–¹³C{¹H} HMBC experiments and are reported using the labeling scheme in Chart 1.

Chart 1. Atom Labels for Complexes 1 and 3 for NMR Spectroscopy Assignments

Commercial reagents and aqueous 30% H_2O_2 were used without further purification. The complex $[PdCl_2(COD)]^{5,6a}$ and the diimine ligand 1,2-bis(mesitylimino)ethane¹² were synthesized according to the literature procedures. The complex $[PdCl(CH_2CMe_2C_6H_5)-(COD)]^{5,6a}$ was prepared under N₂ following the procedure reported by Mirica et al.⁵ with the following slight modification: after addition of the Grignard reagent at -70 °C, the solution was stirred at low temperature and slowly warmed to room temperature over 17 h. Complex $[Pd(CH_2CMe_2C_6H_4)(COD)]^{5,6a}$ was also prepared under N₂ following a procedure from Mirica et al.⁵ with the following minor modification: the reaction was carried out using an ice bath, and a degassed water solution was used to dissolve the base. In both modified syntheses, ¹H NMR spectra matched literature values and yields were improved by 30% and 10%, respectively. Elemental analyses were performed by Laboratoire d'Analyze Élémentaire de l'Université de Montréal. Organic products were analyzed using a Shimadzu GCMS-QP2010 Ultra GC with a DB-5 column. MALDI-TOF mass spectra were collected using an AB Sciex 5800 TOF/TOF mass spectrometer using anthracene as the matrix in a 20:1 matrix:substrate molar ratio.

[Pd^{II}(CH₂CMe₂C₆H₄)(MesN=CHCH=NMes)] (1). To a stirred solution of [Pd(CH₂CMe₂C₆H₄)(COD)] (0.907 g, 2.00 mmol in ether (50 mL) cooled to -65 °C was added a solution of MesN= CHCH=NMes (0.764 g, 2.00 mmol) in ether (20 mL). The mixture was stirred and slowly warmed to room temperature over 17 h, during which time the color of the solution changed from yellow to red. Upon removal of the solvent under reduced pressure, a red solid was formed, which was reprecipitated from ether (5 mL) with hexanes (30 mL). The solid was collected by filtration and dried under vacuum, to give 1 as an air-stable product (0.841 g, 1.58 mmol, 75%). ¹H NMR (C₆D₆, 600 MHz): δ 7.06 (s, H1, 1H), 7.05 (s, H2, 1H), 7.00 (t, J = 7 Hz, H5, 1H), 6.94 (d, J = 7 Hz, H4, 1H), 6.86 (m, H6, 1H), 6.77 (s, H20, 2H), 6.75 (s, H14, 2H), 6.65 (d, J = 8 Hz, H7, 1H), 2.48 (s, H10, 2H), 2.17 (s, H16 and H17, 9H), 2.12 (s, H22, 6H), 2.10 (s, H23, 3H), 1.49 (s, H11, 6H). ¹³C NMR (C_6D_{67} 600 MHz): δ 170.19 (C8), 161.64 (C1), 161.45 (C2), 158.71 (C3), 147.44 (C18), 146.66 (C12), 136.36 (C15), 136.26 (C21), 134.85 (C7), 129.61 (C14), 129.47 (C20), 128.93 (C13 and C19), 124.76 (C5), 124.40 (C6), 122.61 (C4), 48.00 (C9), 47.58 (C10), 34.68 (C11), 21.40 (C23), 21.32 (C17), 18.85 (C22), 18.45 (C16). Note that the correlations do not identify specific rings; therefore, assignments for the C12-C17 and C18-C23 rings, and for imine groups C1 and C2, are arbitrary and could be inverted. MALDI MS (anthracene matrix): calcd m/z 530.2 [Pd(MesN=CHCH= NMes)(CH₂CMe₂C₆H₄)]^{•+}, obsd m/z 530.2. Anal. Calcd for C30H36N2Pd: C, 67.85; H, 6.83; N, 5.28. Found: C, 67.81; H, 7.00; N, 5.14. Red crystals suitable for single-crystal X-ray crystallographic analysis were grown by the slow evaporation of a solution of 1 in ether at room temperature.

[PdBr₂(MesN=CHCH==NMes)] (2a). To a solution of complex 1 (0.020 g, 0.037 mmol) in acetone (2 mL) was added excess Br₂ (10.4 μ L, 0.203 mmol) with stirring. After 5 min the reaction mixture became bright orange. After 2 h the volume of solvent was reduced to ~1 mL and pentane (4 mL) was added to precipitate the product as an orange powder, which was separated by filtration, washed with pentane (3 × 2 mL) and hexanes (3 × 2 mL), and dried under high vacuum (0.021 g, 0.031 mmol, 85%). ¹H NMR (600 MHz, DMSO-*d*₆): δ 8.27 (s, 2H, CH=N), 6.97 (s, 4H, mes-H), 2.29 (s, 18H, 6Me). Anal. Calcd for C₂₀H₂₄Br₂N₂Pd: C, 43.00; H, 4.33; N, 5.01. Found: C, 43.35; H, 4.42; N, 4.85. Orange crystals suitable for single crystal X-ray crystallographic analysis were grown from the slow vapor diffusion of methanol into a DMSO solution of **2a**.

[Pdl₂(MesN=CHCH=NMes)] (2b). Compound 2b was synthesized in a way similar to that for 2a, but using I₂ (0.027 g, 0.092 mmol, 2.5 equiv) instead of Br₂. The dark red solid was formed in 65% yield (0.028 g, 0.036 mmol). ¹H NMR (600 MHz, $(CD_3)_2CO$): δ 8.51 (s, 2H, CH=N), 6.95 (s, 4H, mes-H), 2.30 (m, 18H, 6Me). Anal. Calcd for C₂₀H₂₄I₂N₂Pd: C, 36.81; H, 3.71. Found: C, 36.90; H, 3.71. Orange crystals suitable for single-crystal X-ray crystallographic analysis were grown by the slow evaporation of an acetone solution of 2b at room temperature.

[Pd(MesN=CHCH=NMes)(CH₂CMe₂C₆H₄O)] (3). A vial was charged with a stir bar, 1 (0.040 g, 0.072 mmol), and acetone (4 mL). An H₂O₂ solution (7.5 μ L, 2 equiv, 0.14 mmol) was placed in the vial via a microliter syringe with stirring. The solution was stirred for 3 h, and then the solvent was evaporated to dryness and the residue was washed with hexanes (3 × 3 mL). The crude product was isolated by silica gel column chromatography (9/1 ethyl acetate/pentane) (R_f =

0.087). The product was observed as a dark green band, fractions of this color were combined, and the solvent was removed under vacuum to give 3 as a dark green solid in 50% yield (0.019 mg, 0.036 mmol). NMR ((CD₃)₂CO, 600 MHz): δ (¹H) 8.57 (s, H1,1H), 8.44 (s, H2, 1H), 7.01 (s, H14, 2H), 6.98 (s, H20, 2H), 6.78 (d, 1H, J = 8 Hz, H4), 6.63 (m, 1H, H5), 6.25 (d, 1H, J = 8 Hz, H7), 6.19 (t, J = 8 Hz, H6, 1H), 2.38 (s, H22, 6H), 2.32 (s, H17, 3H), 2.32 (s, H23, 3H), 2.25 (s, H16, 6H), 1.73 (s, H10, 2H), 1.10 (s, H11, 6H); δ (¹³C) 167.14 (C1), 164.40 (C3), 162.85 (C2), 145.26 (C12), 145.09 (C18), 138.85 (C8), 136.85 (C21), 136.30 (C15), 129.54 (C19), 129.38 (C13), 129.25 (C20), 129.11 (C14), 126.12 (C5), 124.89 (C4), 118.98 (C7), 113.44 (C6), 47.58 (C10), 34.50 (C9), 30.84 (C11), 20.76 (C23), 20.69 (C17), 18.39 (C22), 17.67 (C16). Note that the correlations do not identify specific rings,; therefore, assignments for the C12-C17 and C18-C23 rings, and for imine groups C1 and C2, are arbitrary and could be inverted. MALDI MS (anthracene matrix): calcd m/z 546.2 $[Pd(MesN=CHCH=NMes)(CH_2CMe_2OC_6H_4)]^{\bullet+}$, pbsd m/z546.2. Anal. Calcd for $C_{30}H_{36}N_2OPd.H_2O$: C, 63.77; H, 6.78; N, 4.96. Found: C, 64.03; H, 6.67; N, 4.79. Single crystals suitable for Xray crystallographic analysis were grown by the slow evaporation of a benzene solution of 3 at room temperature.

Reaction of Complex 1 with Halogens. A 1:1 solution of iodine and complex 1 in CDCl₃ was monitored by ¹H NMR spectroscopy. The resonances for complex **2b** and 1,1-dimethyl-1,2-dihydrocyclobutabenzene were observed, and complex 1 was completely consumed.^{4b,14} After 2 h, the volume of the solution was reduced and pentane was added to precipitate complex **2b**. The solid was filtered and washed with pentane, and the solvent was removed from the filtrate to give 1,1-dimethyl-1,2-dihydrocyclobutabenzene (CB) as a yellow oil, which was redissolved in CDCl₃ and characterized by ¹H NMR spectroscopy and GC-MS. Yield of CB: 37%, calculated using dimethyl terephthalate as internal standard. ¹H NMR for CB (CDCl₃, 600 MHz): δ (¹H) 8.01 (m, 1H, C₆H₄), 7.17 (m, 1H, C₆H₄), 7.07 (m, 1H, C₆H₄), 7.01 (m, 1H, C₆H₄), 2.95 (s, 2H, CH₂), 1.42 (s, 6H, Me). LR-MS: found *m*/*z* 132.15, calcd for C₁₀H₁₂ *m*/*z* 132.2. The reaction of **1** with bromine was carried out in a similar way.

Reaction of Complex 3 with Halogens. A solution of 3 (0.020 g, 0.036 mmol) and the internal standard dimethyl terephthalate (0.001 g, 0.009 mmol) was prepared in acetone- d_6 (0.7 mL). A ¹H NMR spectrum was obtained to determine the initial ratio of 3 to the internal standard. To this was added a solution of iodine (0.009 g, 0.036 mmol) in acetone- d_6 (0.7 mL), and the reaction was monitored by ¹H NMR spectroscopy. The resonances for complex 2b and 3,3dimethyl-2,3-dihydrobenzofuran (BF) were observed; complex 3 was completely consumed after 2 h.15 The in situ yield of BF was calculated to be 27% relative to the internal standard. Pentane (2 mL) was added to the reaction solution to precipitate complex 2b. The mixture was filtered, and the filtrate was evaporated to give a crude sample of 3,3-dimethyl-2,3-dihydrobenzofuran (BF) as a pale brown oil. The oil was dissolved in CDCl3 and characterized by ¹H NMR spectroscopy and GC-MS. ¹H NMR (CDCl₃, 600 MHz): δ (¹H) 4.22 (s, 2H, OCH₂), 1.33 (s, 6H, Me), in agreement with the literature values.^{15a} The aromatic signals are obscured due to the presence of other signals there. The sample was dissolved in acetone- d_6 to facilitate identification of BF in other reactions. NMR for BF ((CD₃)₂CO, 600 MHz): $\delta({}^{1}\text{H})$ 6.64–6.66 (m, 4H, C₆H₄), 4.19 (s, 2H, OCH2), 1.31 (s, 6H, Me). GC-MS for BF: found m/z 148.2, calcd for C₁₀H₁₂O m/z148.1. The reaction with bromine was carried out in a similar way.

Reaction of Complex 1 with Excess H₂O₂. A vial was charged with a stir bar, complex 1 (0.020 g, 0.036 mmol), and d_6 -acetone (2 mL). A solution of H₂O₂ (7.5 μ L, 4 equiv, 0.14 mmol) was added to the vial via a microliter syringe with stirring. The reaction was monitored by ¹H NMR spectroscopy, as conversion to 3, 2c, and BF occurred. After 10 min relative integration revealed the following species: 1 (6%), 3 (60%), 2c (34%). Within 2 h signals for 2c had completely disappeared but 3 persisted. Formation of the organic product BF was confirmed by comparison to the ¹H NMR spectrum of isolated BF in acetone- d_6 (see above). NMR in (CD₃)₂CO at 600 MHz, resonances tentatively assigned to 2c: δ (¹H) 8.10 (s, 2H, CH= N), 6.91 (s, 4H, mes-CH), 2.11 (s, 18H, Me).

Reaction of Complex 3 with CO. A solution of complex 3 (0.016 g, 0.030 mmol) in acetone- d_6 (3 mL) was stirred under a CO atmosphere at room temperature for 15 min. The solution was filtered to remove the precipitated palladium black and then monitored by ¹H NMR spectroscopy. Complex 3 was completely consumed, and resonances for MesN=CHCH=NMes and 4,4-dimethyl-2-oxo-2H-1-benzopyran (BP; 77% yield) were observed.^{8,12} ¹H NMR for BP (CD₂Cl₂, 600 MHz): δ (¹H) 7.36 (dd, 1H, aryl), 7.27 (m, 1H, aryl), 7.18 (m, 1H, aryl), 7.05 (dd, 1H, aryl), 2.62 (s, 2H, CH₂), 1.35 (s, 6H, 2CH₃). LR-MS for BP: found *m*/*z* 176.15, calcd for C₁₁H₁₂O₂ *m*/*z* 176.21.

X-ray Structure Determinations.²² Data Collection and Processing. A crystal was mounted on a Mitegen polyimide micromount with a small amount of Paratone N oil. All X-ray measurements were made using a Bruker Kappa Axis Apex2 diffractometer at a temperature of 110 K. The frame integration was performed using SAINT, and the resulting raw data were scaled and absorption corrected using a multiscan averaging of symmetry equivalent data using SADABS.

Structure Solution and Refinement. The structures were solved by using the SHELXT program. All non-hydrogen atoms were obtained from the initial solution. The hydrogen atoms were introduced at idealized positions and were allowed to ride on the parent atom. The structural model was fit to the data using full-matrix least squares based on F^2 . The calculated structure factors included corrections for anomalous dispersion from the usual tabulation. The structure was refined using the SHELXL-2014 program from the SHELX suite of crystallographic software.²² Details are given in Table S1 and in the CIF files in the Supporting Information.

DFT Calculations. DFT calculations were carried out for gas phase structures by using the Amsterdam Density Functional program based on the BP functional, with double- ζ basis set and first-order scalar relativistic corrections.²³ Minima were confirmed by vibrational analysis; transition states were not determined. Details are given in the SI.

(19) For example, an isomer of 7 with the PdOHOH group equatorial and aryl group axial, 7a, is calculated to be lower in energy (by 28 kJ mol⁻¹) than 7 and would be accessible by pseudorotation. The oxygen atom insertion could occur in a similar way by C–O reductive elimination from 7a.
