## Abstract

An efficient and general method for the oxidative cleavage of alkenes and alkynes using *tert*-butyl hydroperoxide and indium(III) chloride as catalyst in water to give the corresponding carboxylic acids or ketones has been achieved. The reaction conditions are compatible with sensitive moieties such as peptide bonds, *tert*-butyl carboxylic esters and *N*-Boc-protected tryptophan. The catalyst could be recycled.

The oxidative cleavage of alkenes to carboxylic acids and ketones is a very useful reaction in organic synthesis.<sup>1</sup> The commonly used reagents for this transformation include ozone and several metal oxides such as OsO<sub>4</sub> and RuO<sub>4</sub> in combination with a co-oxidant like NaIO<sub>4</sub> and Oxone.<sup>1,2</sup> Although ozonolysis is a very reliable method, a major issue is the concern for safety; serious or fatal accidents may occur.<sup>3</sup> In addition, ozone gas is highly toxic and damaging to human health and its generation requires special instrumentation. On the other hand OsO<sub>4</sub><sup>4</sup> because of its high volatility and toxicity<sup>4c</sup> is not environmentally acceptable and thus restricts its use for large-scale applications in industry. Ruthenium compounds,<sup>5</sup> being very expensive, are also disadvantaged. An efficient and green protocol for the oxidation of alkenes to the corresponding carboxylic acids using hydrogen peroxide and Na<sub>2</sub>WO<sub>4</sub> as a catalyst has been demonstrated by Noyori et al.<sup>6e,g</sup> Other procedures involving relatively less toxic reagents<sup>6</sup> such as titanium based catalysts<sup>6a</sup> and heteropolyacids on oxide

supports<sup>6b</sup> have been reported. However, they lack general applicability and do not provide satisfactory yields. Therefore, a simple, efficient and safe procedure for oxidative cleavage of olefins, which can excel ozonolysis, is highly desirable. Recently, a gold(I)-catalyzed oxidative cleavage of alkenes to carbonyl compounds using *tert*-butyl hydroperoxide as oxidant and neocuproine as ligand was reported.<sup>6f</sup> This has led us to report our results on the oxidative cleavage of alkenes and alkynes with *t*-BuOOH catalyzed by InCl<sub>3</sub> in H<sub>2</sub>O in the absence of any ligand (Scheme 1).

The experimental procedure is very simple.<sup>7</sup> A mixture of alkene/alkyne, *t*-BuOOH and InCl<sub>3</sub> in water was heated at 90 °C for a certain period of time (TLC). Standard work up provided the product. The aqueous solution of InCl<sub>3</sub> and *t*-BuOH left after work up was recycled for subsequent reactions without any appreciable loss of efficiency. Several experiments were carried out using various reagents and catalysts to optimize the reaction conditions. When *t*-BuOOH was replaced by H<sub>2</sub>O<sub>2</sub> the yields of products did not rise above 25%. InCl<sub>3</sub> gave the best results of the several Lewis acid catalysts investigated (Table 1).

Several diversely substituted alkenes underwent clean cleavage using this procedure to furnish the corresponding products. The results are summarized in Table 2. The open chain mono- substituted (Table 2, entries 1–5) and 1,2-disubstituted (Table 2, entries 6–7) olefins were oxidized to the corresponding carboxylic acids, while the 1,1-disubstituted substrate (Table 2, entry 11) provided the corresponding ketone. The unsubstituted cyclic olefins, cyclohexene (Table 2, entry 8) and cyclooctene (Table 2, entry 10) produced adipic and suberic acids, respectively, in very high yields. These carboxylic acids were obtained as crystals after work up and did not require any further purification. These reactions were also scaled up to multi-gram quantities without any difficulty. Both adipic and suberic acids are industrially very important<sup>6c</sup> and this procedure may serve as an alternative to existing methods.<sup>6</sup> The substituted cyclic olefin, 1-methylcyclohexene (Table 2, entry 9), upon oxidative cleavage, furnished the corresponding keto acid. The exocyclic olefins (entries 12 and 13) were cleaved to the corresponding ketones very efficiently. A few complex olefins containing peptide bonds together with *t*-butyl ester groups and Boc-protected tryptophan moiety (Table 2, entries 14–17) underwent cleavage to the corresponding carboxylic acids without affecting these sensitive functionalities. These substituted peptide carboxylic acids are highly useful compounds and are not easy to prepare using standard methods.<sup>8</sup> The optically active peptides (Table 2, entries 15–17) retained their optical purity under the reaction conditions. The aromatic as well as aliphatic alkynes (Table 2, entries 18–21) were also cleaved to produce the corresponding carboxylic acids without the formation of  $\alpha$ -diketones<sup>9a</sup> or  $\alpha,\alpha'$ -dioxxygenated derivatives.<sup>9b</sup>

Table 1  
Results of the cleavage reaction using different Lewis acids

| Lewis acid        | Yield <sup>a</sup> (%) | Lewis acid        | Yield <sup>a</sup> (%) |
|-------------------|------------------------|-------------------|------------------------|
| CuCl <sub>2</sub> | 38                     | ZnCl <sub>2</sub> | 39                     |
| CeCl <sub>3</sub> | 37                     | TiCl <sub>4</sub> | 55                     |
| FeCl <sub>3</sub> | 42                     | InCl <sub>3</sub> | 84                     |

<sup>a</sup> Yields calculated from <sup>1</sup>H NMR spectra of the crude products.

<sup>a</sup> Isolated yields of pure products (<sup>1</sup>H and <sup>13</sup>C NMR).

The reactions, are in general very clean and high yielding and no side products were isolated. The majority of the products were obtained in high purities (>98%) after work up and a few were purified by crystallization or column chromatography. When the reaction was carried out

Scheme 2.

Fig. 1.

with styrene using *t*-BuOOH alone in the absence of  $\text{InCl}_3$  for a prolonged period (18 h), only 10% of benzoic acid was obtained. On the other hand,  $\text{InCl}_3$  alone without TBHP did not initiate the reaction at all. We suggest that the oxidative cleavage occurred through a number of steps involving epoxide formation followed by hydrolysis with  $\text{H}_2\text{O}$  to give a diol which was then cleaved to a carboxylic acid or ketone (Scheme 2). The isolation of cyclohexene oxide, 1,2-cyclohexanediol and adipic acid at different stages of the cleavage reaction of cyclohexene established the intermediacy of these compounds as outlined in Scheme 2. The progress of the reaction through these intermediates is depicted in Figure 1.

Both pure cyclohexene oxide and 1,2-cyclohexane diol when treated with TBHP/ $\text{InCl}_3$  using this procedure produced adipic acid in nearly quantitative yields. The argument for hydrolysis of the intermediate epoxide by  $\text{H}_2\text{O}$  gained support by the formation of 1-hydroxy-2-methoxycyclohexane when water was replaced by methanol for the cleavage of cyclohexene oxide. The formation of an epoxide from an olefin by TBHP is also precedent.<sup>10</sup>

This procedure has advantages to that catalyzed by  $\text{AuCl}$  in the presence of neocuproine.<sup>6f</sup> Our method does not require any ligand, whereas in other procedures virtually no oxidation occurred without ligand. The compatibility of sensitive functionalities such as a peptide bond, a *tert*-butyl carboxylic ester and *N*-Boc-protected tryptophan and cleavage of exocyclic double bonds were not been addressed in the  $\text{Au(I)}$ -catalyzed method. The yields of products and reaction time in our method are, in general, much better than those catalyzed by  $\text{AuCl}$  particularly, the yield in the cleavage of  $\alpha$ -methyl styrene (Table 2, entry 11), 84% (8 h) compared to 39% (36 h). The catalyst,  $\text{InCl}_3$

is cheaper than  $\text{AuCl}$ . The final products in the present method are carboxylic acids/ketones, whereas in the other procedure, the products are aldehydes. Thus, this method is complementary to the  $\text{Au(I)}$ -catalyzed method.<sup>6f</sup>

In conclusion, we have developed a very clean, efficient and general method for the oxidative cleavage of alkenes and alkynes using *tert*-butyl hydroperoxide and indium(III) chloride as catalysts in water to give the corresponding carboxylic acids or ketones. The advantages of this method are the general applicability to a wide variety of alkenes and alkynes, compatibility with sensitive functionalities, one-pot cleavage of exocyclic double bonds to ketones and high yields. The use of water as the reaction medium, reusability of the aqueous solution of catalyst and no need for waste disposal, make this procedure greener, safe and potentially useful for industrial applications.

- Representative procedure for the oxidative cleavage of cyclohexene to adipic acid (Table 2, entry 8). A mixture of cyclohexene (82 mg,

1 mmol), indium(III) chloride (44 mg, 20 mol %) and *tert*-butyl hydroperoxide (0.5 mL, 70%, 3.8 mmol) in water (2.5 mL) was heated at 90 °C for 9 h (TLC). The cooled reaction mixture was then extracted with ethyl acetate (3 × 10 mL) and the extract was washed with brine (2 × 5 mL) and dried (Na<sub>2</sub>SO<sub>4</sub>). Evaporation of the solvent furnished crystals of adipic acid (134 mg, 92%) of more than 98% purity. (If necessary, the crude products were purified by column chromatography over silica gel.) The melting point and spectroscopic data (IR, <sup>1</sup>H and <sup>13</sup>C NMR) of the products were in good agreement with those of an authentic sample of adipic acid.<sup>11</sup> The aqueous solution of InCl<sub>3</sub> and *t*-BuOH left after work up, was recycled for six subsequent reactions without any appreciable loss of efficiency.

This procedure was followed for the oxidative cleavage of all the alkenes and alkynes listed in Table 2. Although this procedure was based on mmol scale, the reaction was also carried out on multigram quantities without any difficulty. All the products except four (Table 2, entries 14–17) are known compounds and were identified by comparison of their melting points, when applicable, and spectroscopic data (IR, <sup>1</sup>H and <sup>13</sup>C NMR) with those reported (see references in Table 2). The novel compounds (Table 2, entries 14–17) were characterized by their spectroscopic data (IR, <sup>1</sup>H and <sup>13</sup>C NMR, HRMS) which are provided below.

*9-(2-Benzoyloxycarbonyl-ethylcarbamoyl)-nonanoic acid* (Table 2, entry 14): Yellow viscous oil; IR (neat) 3300, 2929, 2856, 1733, 1653, 1170 cm<sup>-1</sup>; <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>) δ 1.02–1.21 (m, 8H), 1.53–1.55 (m, 4H), 2.11 (t, *J* = 7.56 Hz, 2H), 2.27–2.41 (m, 2H), 2.57 (t, *J* = 6.01 Hz, 2H), 3.50 (q, *J* = 5.91 Hz, 2H), 5.12 (s, 2H), 6.14 (br s, 1H), 7.29–7.38 (m, 5H); <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>) δ 23.8, 25.6, 29.0 (2C), 29.1, 29.2, 34.2, 34.9, 36.7, 43.8, 66.6, 128.3 (2C), 128.5, 128.7 (2C), 135.7, 172.6, 173.4, 177.3; HRMS *m/z* calcd for C<sub>20</sub>H<sub>29</sub>NO<sub>5</sub>Na [M+Na]<sup>+</sup> 386.2046; found: 386.2127.

*9-(1-Methoxycarbonyl-ethyl carbamoyl)-nonanoic acid* (Table 2, entry 15): yellow viscous liquid; IR (neat) 3388, 3288, 2931, 2856, 1737, 1651, 1546, 1215, 1026, 1004 cm<sup>-1</sup>; <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub> + DMSO-*d*<sub>6</sub>) δ 1.10–1.23 (m, 12H), 1.30–1.44 (m, 3H), 1.98–2.12 (m, 4H), 3.56 (s, 3H), 4.22–4.30 (m, 1H), 7.72 (d, *J* = 5.98 Hz,

1H); <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub> + DMSO-*d*<sub>6</sub>) δ 16.2, 24.2, 27.6, 27.7, 27.8, 27.9, 28.1, 34.3, 34.4, 46.5, 50.7, 171.9, 172.2, 173.5; HRMS *m/z* calcd for C<sub>14</sub>H<sub>25</sub>NO<sub>5</sub>K [M+K]<sup>+</sup> 326.1733; found: 326.1880; [α]<sub>D</sub><sup>26</sup> –18.9 (c 5.00, CHCl<sub>3</sub>).

*9-(1-*tert*-Butoxycarbonyl-2-phenyl-ethyl carbamoyl)-nonanoic acid* (Table 2, entry 16): viscous yellow liquid; IR (neat) 3062, 3028, 2927, 2854, 1712, 1643, 1481, 1242, 1193, 1159 cm<sup>-1</sup>; <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>) δ 1.18–1.42 (m, 16H), 1.53–1.60 (m, 5H), 1.97–2.14 (m, 2H), 2.27 (t, *J* = 7.39 Hz, 2H), 2.96 (d, *J* = 5.93 Hz, 2H), 4.71 (q, *J* = 7.07 Hz, 1H), 7.02–7.20 (m, 5H); <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>) δ 25.0, 28.3, 29.3 (2C), 29.4 (3C), 29.5, 29.7, 30.0, 34.4 (2C), 53.8, 82.9, 127.3, 128.8 (2C), 129.7 (2C), 135.6, 179.8, 179.9, 180.1; HRMS *m/z* calcd for C<sub>23</sub>H<sub>35</sub>NO<sub>5</sub>Na [M+Na]<sup>+</sup> 428.2413; found: 428.2415; [α]<sub>D</sub><sup>26</sup> +5.1 (c 5.00, CHCl<sub>3</sub>).

*3-[2-(9-Carboxy-nonanoylamino)-2-methoxycarbonyl-ethyl]-indole-1-carboxylic acid *tert*-butyl ester* (Table 2, entry 17): yellow viscous liquid; IR (neat) 3435, 3250, 2850, 1720, 1658, 1216, 1053, 1028, 1007, 823, 702 cm<sup>-1</sup>; <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>) δ 1.23–1.45 (m, 10H), 1.56–1.68 (m, 9H), 1.99–2.04 (m, 4H), 2.15 (t, *J* = 7.45 Hz, 2H), 3.15–3.29 (m, 2H), 3.67 (s, 3H), 4.08 (q, *J* = 7.14 Hz, 1H), 7.17–7.46 (m, 5H), 8.07 (d, *J* = 7.05 Hz, 1H); <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>) δ 25.5, 28.0 (3C), 28.8, 29.0, 29.1, 29.2, 29.3, 33.7, 36.5, 52.3, 52.4, 60.4, 83.7, 114.9, 115.3, 118.8, 122.5, 124.0, 124.5, 130.5, 135.2, 172.2, 173.1, 174.9, 175.8; HRMS *m/z* calcd for C<sub>27</sub>H<sub>38</sub>N<sub>2</sub>O<sub>7</sub>K [M+K]<sup>+</sup> 541.2316; found: 541.2417; [α]<sub>D</sub><sup>27</sup> +37.3 (c 5.00, CHCl<sub>3</sub>).
