Supporting Information

ABSTRACT: Described are experiments demonstrating incorporation of cyanide cofactors and hydride substrate into [NiFe]-hydrogenase (H_2ase) active site models. Complexes of the type $(CO)_2(CN)_2Fe(pdt)Ni(dxpe)$ ($dxpe = dppe$, **1**; $dxpe = dcpe$, **2**) bind the Lewis acid $B(C_6F_5)_3$ (BAR^F_3) to give the adducts $(CO)_2(CNBAR^F_3)_2Fe(pdt)Ni(dxpe)$, $(1(BAR^F_3)_2, 2(BAR^F_3)_2)$. Upon decarbonylation using amine oxides, these adducts react with H_2 to give hydrido derivatives $[(CO)(CNBAR^F_3)_2Fe(H)(pdt)Ni(dxpe)]^-$ ($dxpe = dppe$, $[H_3(BAR^F_3)_2]^-$; $dxpe = dcpe$, $[H_4(BAR^F_3)_2]^-$). Crystallographic analysis shows that $Et_4N[H_3(BAR^F_3)_2]$ generally resembles the active site of the enzyme in the reduced, hydride-containing states (Ni–C/R). The Fe–H···Ni center is unsymmetrical with $r_{Fe-H} = 1.51(3)$ Å and $r_{Ni-H} = 1.71(3)$ Å. Both crystallographic and ^{19}F NMR analyses show that the $CNBAR^F_3$ ligands occupy basal and apical sites. Unlike cationic Ni–Fe hydrides, $[H_3(BAR^F_3)_2]^-$ and $[H_4(BAR^F_3)_2]^-$ oxidize at mild potentials, near the $Fe^{+}/0$ couple. Electrochemical measurements indicate that in the presence of base, $[H_3(BAR^F_3)_2]^-$ catalyzes the oxidation of H_2 . NMR evidence indicates dihydrogen bonding between these anionic hydrides and R_3NH^+ salts, which is relevant to the mechanism of hydrogenogenesis. In the case of $Et_4N[H_3(BAR^F_3)_2]$, strong acids such as HCl induce H_2 release to give the chloride $Et_4N[(CO)(CNBAR^F_3)_2Fe(Cl)(pdt)Ni(dppe)]$.

INTRODUCTION

The hydrogenases (H_2ases) are represented by three main families of enzymes defined by the metals at their active sites, the $[FeFe]$ -, $[Fe]$ -, and $[NiFe]$ - H_2ases .¹ Other enzymes consume or produce hydrogen,² but the $[FeFe]$ - and $[NiFe]$ - H_2ases are renowned for their ability to catalyze the oxidation of H_2 and reduction of protons at high rates and low overpotentials.³

The active sites of the H_2ases are characterized by the presence of several remarkable cofactors (Figure 1). Crystallographic and spectroscopic analyses consistently point to the presence of $Fe(CO)_x(CN)_y$ sites in both types of redox active H_2ases .⁴ The diatomic cofactors are unusual in biology.⁵ As indicated by close

contacts between otherwise nonbonded heteroatoms, the Fe–CN centers engage in hydrogen bonding. For example, in the $[NiFe]$ - H_2ase from *D. fructosovorans*, one cyanide ligand hydrogen bonds with serine 499 ($N\cdots N$, $N\cdots O = 2.98$, 2.88 Å, respectively). The second cyanide interacts with arginine 476, with $N\cdots N$ distances of 2.87 and 3.25 Å.⁶ Some of these amino acids can be mutated with retention of catalytic activity,⁷ which suggests that the N-terminus of the cyanide cofactors could be modified in models as well.

Motivated both by the novelty of the active site as well as by possible practical applications, much effort has been invested into the structural and functional models of the $[NiFe]$ - H_2ase active site.^{1,8} Since 2009, several nickel–iron hydrides have been reported, but all of these models feature $Fe(CO)_{3-x}(PR_3)_x$ centers ($x = 0, 1, 2$).^{9–12} In contrast to these cationic models, the active site is expected to be anionic because six ligands, two cyanide cofactors and four thiolate groups, are anionic.¹³ Incorporation of cyanide cofactors in models is avoided because of the reactivity of the basic nitrogen site of cyanide.¹⁴ Structural modes for a CO-inhibited state of the $[NiFe]$ - H_2ases with cyanide cofactors have been reported, $(CN)_2(CO)_2Fe(SR)_2Ni(dppe)$ ($dppe = (C_2H_4(PPh_2)_2)$)¹⁵ and $[(CN)_2(CO)_2Fe(SR)_2Ni(S_2CNET_2)]^-$.¹⁶ Both complexes feature $Fe(CO)_2(CN)_2$ centers bound to $Ni(SR)_2L_2$ sites. These

complexes exhibit no biomimetic reactivity because of the coordinatively saturated nature of the Fe(CN)₂(CO)₂(SR)₂ sites.

This Article describes a method for modifying Fe–CN centers to suppress their high basicity¹⁴ but retain the charge provided by the anionic cofactors. The approach entails attaching organoboranes to the Fe–CN groups. Although novel for metallobiochemistry, the interaction of boranes with metal cyanides is well-known¹⁷ and is exploited in commercial hydrocyanation catalysis.¹⁸

In view of the inertness of cyanide-containing models for the [NiFe]-H₂ases, attachment of boranes to the Fe–CN centers was expected to both labilize one CO ligand and suppress reactions of the Fe–CN centers, giving rise to reactive Ni^{II}–Fe^{II} centers capable of capturing a hydride substrate from dihydrogen.

RESULTS AND DISCUSSION

N-Protected Active Site Models. Modeling efforts focused on the dicyano Ni–Fe dithiolate **1**, which was prepared by combining NiCl₂(dppe) and [Fe(CN)₂(pdt)(CO)₂]^{2–}. Initial efforts to induce reactivity reminiscent of the H₂ases focused on the decarbonylation of this species. The FT-IR spectrum of **1** exhibits a relatively high frequency ν_{CO} band at 2053 cm^{–1}, suggesting that CO would be labile. UV-irradiation of a THF solution of **1**, however, afforded only insoluble solids, which are tentatively attributed to the formation of Fe–CN–M (M = Fe, Ni) linkages. Solutions of **1** were also found to be inert toward the decarbonylating agent Me₃NO.

Next examined was the use of boranes to protect the Fe–CN centers while also electrophilically activating the iron center. A variety of triarylboranes were found to form adducts with **1**, but this work focuses on B(C₆F₅)₃ (BAr^F₃). Adducts of this strong Lewis acid are often highly soluble in nonpolar solvents compatible with H₂ activation experiments.¹⁹ Treatment of CH₂Cl₂ solutions of **1** with 2 equiv of BAr^F₃ quantitatively afforded the 2:1 adduct (CO)₂(CNBAr^F₃)₂Fe(pdt)Ni(dppe), **1**(BAr^F₃)₂ (Scheme 1). The attachment of BAr^F₃ strongly affects the ν_{CN} and ν_{CO} bands, resulting in shifts of about 100 and 50 cm^{–1}, respectively (Table S1). The pattern of the ν_{CO/CN} bands is similar for the precursor and the adduct, consistent with retention of the *cis*-CO/*trans*-CN arrangement.³¹P and ¹⁹F NMR spectra are also consistent with the proposed stereochemistry.

The structure of **1**(BAr^F₃)₂ was verified by X-ray crystallography (Figure 2). Because of the steric bulk of the BAr^F₃ groups, the Ni–Fe distance increased from 2.809 in **1** to 3.218 Å in the adduct.¹⁵ Similarly, the Ni–S–Fe angles opened from 75.98° to 86.60°. The BAr^F₃ substituents only subtly affect the diatomic ligands: the Fe–CN bonds are slightly elongated (Δ_{avg} = 0.03 Å), and the Fe–CO bond is slightly shortened (Δ_{avg} = –0.03 Å). The

Figure 2. Structure of [(CO)₂(CNBAr^F₃)₂Fe(pdt)Ni(dppe)], **1**(BAr^F₃)₂, with ellipsoids shown at 50% probability and with H atoms omitted for clarity. Phenyl and pentafluorophenyl groups are de-emphasized for clarity.

weak Ni...CN π-interaction (2.421 Å) apparent in **1**¹⁵ is absent in **1**(BAr^F₃)₂.

To examine the effects of the basicity of nickel, (CO)₂(CN)₂Fe(pdt)Ni(dcpe) (**2**), featuring the highly basic ligand dcpe (C₂H₄(P(C₆H₁₁)₂)₂), was also investigated. IR and ³¹P NMR spectroscopy shows that **2** exists as a mixture of isomers, consisting of both the *cis*-CO/*trans*-CN arrangement (as seen in **1**) and the *cis*-CO/*cis*-CN arrangement. The decreased Lewis acidity of the Ni(dcpe) center, associated with the strong donor properties of dcpe,²⁰ is proposed to weaken the Ni–NCFe interaction, giving rise to the second isomer. Much like **1**, **2** was found to be unreactive toward Me₃NO and unstable in ambient light. Complexation of **2** with BAr^F₃ gave a pair of isomeric adducts of the formula (CO)₂(CNBAr^F₃)₂Fe(pdt)Ni(dcpe), **2**(BAr^F₃)₂. Over the course of several hours, this mixture converted to the *cis*-CO/*trans*-CN arrangement seen for **1**(BAr^F₃)₂.

The attachment of BAr^F₃ to the cyanide ligands stabilizes isomers not observed in **1** and **2**. As determined by ¹⁹F and ³¹P NMR spectroscopy, the *cis*-CO/*trans*-CN isomer of **1**(BAr^F₃)₂ converted to the *cis*-CO/*cis*-CN isomer upon heating at 60 °C. Upon UV-irradiation (365 nm), **1**(BAr^F₃)₂ converted to the *trans*-CO/*cis*-CN isomer as well as a small amount of the *cis*-CO/*cis*-CN isomer. Upon standing, *trans*-CO/*cis*-CN reverted to one of the two *cis*/*cis* isomers. Irradiation of the latter regenerated the *trans*-CO/*cis*-CN isomer. In no case was the *cis*-CO/*trans*-

CN isomer of $1(\text{BAr}^{\text{F}}_3)_2$ observed to reform, thus, it is apparently a kinetically stabilized isomer.

Irradiation of the *cis*-CO/*trans*-CN isomer of $2(\text{BAr}^{\text{F}}_3)_2$ gave the *trans*-CO/*cis*-CN isomer. Unlike in $1(\text{BAr}^{\text{F}}_3)_2$, the *cis*-CO/*cis*-CN isomer of $2(\text{BAr}^{\text{F}}_3)_2$ was not found to reform. Iron carbonyl complexes with high frequency ν_{CO} bands are typically photolabile. Indeed, photolysis of *cis*-CO/*trans*-CN $1(\text{BAr}^{\text{F}}_3)_2$ under an atmosphere of ^{13}CO gave complete exchange of CO while forming the *trans*-CO/*cis*-CN isomer. Furthermore, the photoisomerization of $1(\text{BAr}^{\text{F}}_3)_2$ was found to be inhibited by CO. These results are consistent with a dissociative pathway for the photoisomerization of $1(\text{BAr}^{\text{F}}_3)_2$ and $2(\text{BAr}^{\text{F}}_3)_2$.

Hydride Derivatives. Being coordinatively saturated, the adducts $1(\text{BAr}^{\text{F}}_3)_2$ and $2(\text{BAr}^{\text{F}}_3)_2$ are unreactive toward H_2 . Addition of a decarbonylation agent, however, was found to induce rapid uptake of H_2 (eq 1).

Thus, treatment of a CH_2Cl_2 solution of $1(\text{BAr}^{\text{F}}_3)_2$ with 1.2 equiv of an amine oxide under an atmosphere of H_2 afforded the hydride $[(\text{CO})(\text{CNBAr}^{\text{F}}_3)_2\text{Fe}(\text{H})(\text{pdt})\text{Ni}(\text{dppe})]^-$, which was isolated as the salt $\text{Et}_4\text{N}[\text{H}3(\text{BAr}^{\text{F}}_3)_2]$. The use of D_2 in place of H_2 gave $\text{Et}_4\text{N}[\text{D}3(\text{BAr}^{\text{F}}_3)_2]$, as verified by ^1H and ^2H NMR analyses. The decarbonylation agent Me_3NO gave an initial mixture of isomers with the $\text{CNBAr}^{\text{F}}_3$ ligands in dibasal (b/b) and apical-basal (a/b) arrangements in a 1:9.5 ratio. Upon standing in solution, the b/b isomer converted solely to the a/b isomer. Decarbonylation of $1(\text{BAr}^{\text{F}}_3)_2$ with *N*-methylmorpholine-*N*-oxide (NMO) produced the b/b isomer as the major species (2.5:1 b/b:a/b ratio). Similarly, decarbonylation of $2(\text{BAr}^{\text{F}}_3)_2$ under H_2 produced the a/b isomer of $\text{Et}_4\text{N}[(\text{CO})(\text{CNBAr}^{\text{F}}_3)_2\text{Fe}(\text{H})(\text{pdt})\text{Ni}(\text{dcpe})]^-$ ($\text{Et}_4\text{N}[\text{H}4(\text{BAr}^{\text{F}}_3)_2]$) when Me_3NO was used as a decarbonylating agent with no b/b isomer observed.

The hydrides $[\text{H}3(\text{BAr}^{\text{F}}_3)_2]^-$ and $[\text{H}4(\text{BAr}^{\text{F}}_3)_2]^-$ were also produced using conventional hydride sources instead of H_2 . Thus, treatment of $1(\text{BAr}^{\text{F}}_3)_2$ with amine oxides followed by Et_4NBH_4 gave $\text{Et}_4\text{N}[\text{H}3(\text{BAr}^{\text{F}}_3)_2]$. However, attempted synthesis of $\text{Et}_4\text{N}[\text{H}4(\text{BAr}^{\text{F}}_3)_2]$ by treatment of $2(\text{BAr}^{\text{F}}_3)_2$ with amine oxides and Et_4NBH_4 produced more complicated results, yielding both mono- and dicarbonyl hydrides. Overall, H_2 is a milder, more selective reagent for generating hydrido complexes.

As observed in the enzymes, the IR spectra of $[\text{H}3(\text{BAr}^{\text{F}}_3)_2]^-$ and $[\text{H}4(\text{BAr}^{\text{F}}_3)_2]^-$ display two ν_{CN} and one ν_{CO} bands. The energy for ν_{CO} of $[\text{H}4(\text{BAr}^{\text{F}}_3)_2]^-$ is 11 cm^{-1} lower than that of $[\text{H}3(\text{BAr}^{\text{F}}_3)_2]^-$, indicating that changes at the Ni center (dppe vs dcpe) influence the Fe site. Values of ν_{CO} for $[\text{H}3(\text{BAr}^{\text{F}}_3)_2]^-$ and $[\text{H}4(\text{BAr}^{\text{F}}_3)_2]^-$ were found to be within the range observed for the Ni-R state of $[\text{NiFe}]\text{-H}_2\text{ase}$ (Table 1).

Structure of $\text{Et}_4\text{N}[\text{H}3(\text{BAr}^{\text{F}}_3)_2]$ and Comparisons with Enzyme Active Site. The structure of $[\text{H}3(\text{BAr}^{\text{F}}_3)_2]^-$ was confirmed by single-crystal X-ray diffraction (Figure 3). The hydride present in $[\text{H}3(\text{BAr}^{\text{F}}_3)_2]^-$ was located in the difference Fourier map and refined isotropically. The Fe–H distance of

Figure 3. Structure of the anion in $\text{Et}_4\text{N}[(\text{CO})(\text{CNBAr}^{\text{F}}_3)_2\text{Fe}(\text{H})(\text{pdt})\text{Ni}(\text{dppe})]^-$, $\text{Et}_4\text{N}[\text{H}3(\text{BAr}^{\text{F}}_3)_2]$, with ellipsoids shown at 50% probability and H atoms except for the bridging hydride omitted. Phenyl and pentafluorophenyl groups are de-emphasized for clarity.

$1.51(3)\text{ \AA}$ is shorter than the Ni–H bond ($1.71(3)\text{ \AA}$). In several respects, the structure of $[\text{H}3(\text{BAr}^{\text{F}}_3)_2]^-$ resembles the high-resolution ($1.4, 1.5\text{ \AA}$) structures of the hydride-containing states (Ni–C/R) of *D. vulgaris* (Table 2).²² The Fe···Ni distance of $2.5497(5)\text{ \AA}$ reasonably matches the values 2.59 and $2.57\text{ \AA}$ found in these hydride-containing states. Reminiscent of the active site, the coordination geometry of the NiS_2P_2 center is distorted from square planar, with a twist angle between the NiS_2 and NiP_2 planes of 34.53° . Like the enzyme, iron is bound to one CO and two CN-derived ligands, although the locations of the CO and the one $\text{CNBAr}^{\text{F}}_3$ are interchanged relative to the enzyme.

Reactivity of the Hydrido Complexes. The redox properties of $[\text{H}3(\text{BAr}^{\text{F}}_3)_2]^-$ and $[\text{H}4(\text{BAr}^{\text{F}}_3)_2]^-$ were assessed by cyclic voltammetry on CH_2Cl_2 solutions. These results underscore the influence of anionic ligands on the Fe site. Both hydrides oxidize at mild potentials: -0.08 V vs $\text{Fc}^{0/+}$ ($i_{\text{pc}}/i_{\text{pa}} = 0.43$, scan rate = 0.1 V/s) for $\text{Et}_4\text{N}[\text{H}3(\text{BAr}^{\text{F}}_3)_2]$ and -0.10 V ($i_{\text{pc}}/i_{\text{pa}} = 0.69$, scan rate = 0.1 V/s) for $\text{Et}_4\text{N}[\text{H}4(\text{BAr}^{\text{F}}_3)_2]$ (Figures S29, S30). The insensitivity of the $[\text{H}3(\text{BAr}^{\text{F}}_3)_2]^{-/0}$ versus $[\text{H}4(\text{BAr}^{\text{F}}_3)_2]^{-/0}$ couples to the diphosphine suggests that oxidation is localized on Fe. In the enzyme, oxidation of the Ni–R state occurs at Ni.

Reflecting their anionic character, both complexes reduce at more negative potentials than previously reported NiFe hydrides.

A reversible reduction was observed for $\text{Et}_4\text{N}[\text{H3}(\text{BAR}^{\text{F}_3})_2]$ at -1.99 V (Figure S28), but no reduction was observed for $\text{Et}_4\text{N}[\text{H4}(\text{BAR}^{\text{F}_3})_2]$ within the potential window of CH_2Cl_2 (i.e., less reducing than -2.5 V). Cationic Ni–Fe hydrides, based on $\text{Fe}(\text{CO})_{3-x}(\text{PR}_3)_x$ centers reduce at milder potentials (-1.33 to -1.56 V vs $\text{Fc}^{0/+}$).^{10,11} Reduction potentials for those cationic $\text{Ni}^{\text{II}}\text{--Fe}^{\text{II}}$ hydrides are sensitive to substitution at Ni (dppe vs dcpe) and Fe (CO vs PR_3).^{10,11}

The acid–base properties of $[\text{H3}(\text{BAR}^{\text{F}_3})_2]^-$ and $[\text{H4}(\text{BAR}^{\text{F}_3})_2]^-$ were examined, with limited success. Unlike cationic Ni–Fe hydrides, which exhibit $\text{p}K_{\text{a}}^{\text{MeCN}}$ near 14, CH_2Cl_2 solution of $[\text{H3}(\text{BAR}^{\text{F}_3})_2]^-$ did not undergo deprotonation upon treatment with the strong base DBU ($\text{p}K_{\text{a}}^{\text{MeCN}} = 24.34$). Solution of $[\text{H3}(\text{BAR}^{\text{F}_3})_2]^-$ exhibits no exchange with D_2O .

$\text{Et}_4\text{N}[\text{H3}(\text{BAR}^{\text{F}_3})_2]$ was found to be an electrocatalyst for the oxidation of H_2 . When a solution was examined by cyclic voltammetry under 1 atm of H_2 , the current at -0.08 V, corresponding to the $[\text{H3}(\text{BAR}^{\text{F}_3})_2]^{-/0}$ couple, was found to increase upon addition of the base DBU (see the Supporting Information).

Dihydrogen Bonding. The solution properties of $[\text{H3}(\text{BAR}^{\text{F}_3})_2]^-$ are indicative of its hydridic character, consistent with its resemblance to the hydrogen-evolving state Ni–R. Specifically, the high field ^1H NMR signal of $\text{Et}_4\text{N}[\text{H3}(\text{BAR}^{\text{F}_3})_2]$ is sensitive to the presence of protic reagents that engage in dihydrogen bonding. For example, the addition of $\text{HNMe}_3[\text{BAR}^{\text{F}_3}]$ ($\text{BAR}^{\text{F}_3} = \text{B}(\text{C}_6\text{H}_3-3,5\text{-(CF}_3)_2)_4$; $\text{p}K_{\text{a}}^{\text{MeCN}} = 17.61$)²³ shifts the hydride signal (δ_{H}) by about 2 ppm (Figure 4, eq 2). The dependence of δ_{H} on the concentration of HNMe_3^+ is

consistent with an equilibrium constant of $(9.0 \pm 1.0) \times 10^3$ L/mol in CD_2Cl_2 (20°C). Dihydrogen bonding is also evident in

Figure 4. ^1H NMR chemical shift for $\text{Et}_4\text{N}[\text{H3}(\text{BAR}^{\text{F}_3})_2]$ upon titration with $\text{HNMe}_3[\text{BAR}^{\text{F}_3}]$ in CD_2Cl_2 (20°C). Inset: ^1H NMR (500 MHz) spectra of the titration of $\text{Et}_4\text{N}[\text{H3}(\text{BAR}^{\text{F}_3})_2]$ with $\text{HNMe}_3[\text{BAR}^{\text{F}_3}]$ in CD_2Cl_2 (20°C): (a) 0, (b) 1.0, (c) 2.0, (d) 3.0, and (e) 4.0 equiv.

the ^1H NMR spectra when $[\text{H4}(\text{BAR}^{\text{F}_3})_2]^-$ was titrated with $[\text{pyrrolidinium}]\text{BAR}^{\text{F}_3}$ ($\text{p}K_{\text{a}}^{\text{MeCN}} = 19.56$).²⁴ Although competitive with degradation of the complex, $[\text{H3}(\text{BAR}^{\text{F}_3})_2]^-$ was found to undergo H/D scrambling with D_2 , forming HD. This process occurs only in the presence of HNMe_3^+ .

Although weak acids form dihydrogen bonds with $[\text{H3}(\text{BAR}^{\text{F}_3})_2]^-$, stronger acids (e.g., PhNH_3^+ $\text{p}K_{\text{a}}^{\text{MeCN}} = 10.62$) induce release ~ 1 equiv of H_2 . Using HCl, the unsaturated product is trapped as the chloride adduct $[\text{Cl3}(\text{BAR}^{\text{F}_3})_2]^-$. The complex $[\text{Cl3}(\text{BAR}^{\text{F}_3})_2]^-$ was independently prepared by the reaction of $\text{I}(\text{BAR}^{\text{F}_3})_2$ with Me_3NO and Et_4NCl .

CONCLUSIONS

Borane protecting groups enable the preparation of the first models of the $[\text{NiFe}]\text{--H}_2$ ases with biomimetic ligation at Fe. The protecting groups suppress reactions at the Fe–CN centers, while retaining the anionic charge that is characteristic of these active sites.

Similar to work with the enzyme,²¹ models in this work were obtained in an inhibited state. Unlike the enzyme,²⁵ the CO-inhibited NiFe models contain an extra CO ligand on Fe.²⁶ Upon decarbonylation, the borane-protected Ni–Fe derivatives abstract hydride from H_2 . The generation of hydrides from H_2 is unusual in H_2 ase models^{12,27} but is a key reaction of the enzyme. On the basis of structural and ν_{CO} data, these models compare well with the Ni–R state.²⁸

The redox properties of the hydrides $[\text{H3}(\text{BAR}^{\text{F}_3})_2]^-$ and $[\text{H4}(\text{BAR}^{\text{F}_3})_2]^-$ provide insights into the design of improved active site models. Because the basicities of dppe and dcpe differ greatly²⁰ and the oxidation potentials differ by only 20 mV, these oxidations are assigned to the $\text{Fe}^{\text{II/III}}$ couple. In contrast, oxidation of the Ni–R state to the Ni–C state is localized on nickel, that is, a $\text{Ni}^{\text{II}}\text{--Fe}^{\text{II}}/\text{Ni}^{\text{III}}\text{--Fe}^{\text{II}}$ couple.²⁹ These findings point to the limitations of diphosphines as mimics for the terminal ligands on the Ni site. As suggested with a recent model,³⁰ the terminal thiolate ligands in the enzyme¹ change their protonation state upon redox of the Ni center. Future models could benefit by including terminal ligands that have ionizable protons such as RSH.

As compared to cationic nickel–iron hydrides,^{10–12} the anionic models exhibit more biomimetic electrochemical and acid–base properties. Most importantly, anionic nickel–iron hydrides have hydridic character³¹ as indicated by NMR studies showing dihydrogen bonding, which leads to hydrogen evolution. On the basis of these results, a similar dihydrogen bond in the Ni–R state is proposed to precede H₂ evolution (Figure 5).

Figure 5. Dihydrogen bonding in $[\text{H}_3(\text{BAr}^{\text{F}_3})_2]^-$ and the analogous interaction proposed for Ni–R.

Bridging hydrides in related systems have protic character and do not engage in dihydrogen bonding.³² Dihydrogen bonding involving terminal iron hydrides is observed in models for the active site of the $[\text{FeFe}]$ -H₂ases.³³ Thus, it appears that the hydrides of $[\text{FeFe}]$ - and $[\text{NiFe}]$ -H₂ases (in the Ni–R state) are similar in being hydridic.

EXPERIMENTAL SECTION

All procedures were carried out in a nitrogen-filled MBraun glovebox or using standard Schlenk techniques. All solvents were degassed by sparging with nitrogen and dried by passage through activated alumina. IR spectra were recorded on a Perkin-Elmer Spectrum 100. Cyclic voltammetry was performed under argon at room temperature using a CHI 630D potentiostat with glassy carbon working electrode, Pt wire counter electrode and the pseudoreference electrode Ag wire, and with Fc internal standard. Production of H₂ was quantified by gas chromatography on a column packed with 5 Å molecular sieves (carrier gas: Ar), using an Agilent 7820A instrument equipped with a thermal conductivity detector. The response factor for H₂/CH₄ was 3.8 under experimental conditions as established by calibration with standard H₂–CH₄ mixtures. NMR spectra were recorded on a Varian Unity 500 MHz NMR spectrometer. Signals for ¹⁹F and ³¹P NMR spectra were referenced using external standards of 1% CFCl₃ in CDCl₃ and 85% H₃PO₄, respectively. ¹H NMR spectra were referenced to internal solvent signals. CD₂Cl₂ (Cambridge Isotope Laboratories) was dried over CaH₂ before being vacuum distilled onto activated 4 Å molecular sieves. B(C₆F₅)₃ (Boulder Scientific) was sublimed under vacuum at 90 °C. Literature routes were followed for NiCl₂(dppe),⁹ NiCl₂(dcpe),¹¹ Et₄N[Fe(CO)₄(CN)], K₂pdt,¹⁶ and Et₄N[FeBr(CO)₃(CN)₂].¹⁶

Revised Synthesis of (CO)₂(CN)₂Fe(pdt)Ni(dppe), 1. A solution of Et₄N[FeBr(CO)₃(CN)₂] (0.900 g, 2.22 mmol) in MeOH (100 mL) was treated with a solution of K₂pdt (0.410 g, 2.22 mmol) in MeOH (50 mL). The mixture was allowed to stir for 3 h at which time the solvent was removed under vacuum. NiCl₂(dppe) (1.17 g, 2.22 mmol) was added along with 100 mL of MeCN, and the mixture was stirred for 15 min. The mixture was filtered, and the solvent was removed from the filtrate under vacuum. The crude product was extracted into THF, and the crude product was precipitated from the filtered extract upon the addition of pentane. The crude product was dissolved in MeCN and loaded onto a neutral alumina column (Brockmann Level I). A faint red band was washed off the column with MeCN. The product eluted with MeOH as a red band. The solution was evaporated under vacuum, and the residue was extracted into THF. This solution was filtered through Celite, and product was precipitated from the filtrate with pentane. The product¹⁶ was collected by filtration and dried under vacuum. Yield: 0.958 g (59%).

(CO)₂(CN)₂Fe(pdt)Ni(dcpe), 2. A solution of Et₄N[FeBr(CO)₃(CN)₂] (0.500 g, 1.23 mmol) in MeOH (20 mL) was treated with a solution of K₂pdt (0.228 g, 1.23 mmol) in MeOH (20 mL). The mixture was let to stir for 3 h at which time the solvent was removed under vacuum. In the absence of light, the residue was extracted into 20 mL of MeCN, and the mixture was treated with a suspension of NiCl₂(dcpe) (0.682 g, 1.23 mmol) in MeCN (20 mL). After being stirred for 15 min, the mixture was filtered, and the solvent was stripped from the filtrate. The crude product was extracted into 20 mL of THF, the mixture was filtered, and the product was precipitated from the filtrate upon the addition of pentane. Unlike 1, 2 did not require further purification by column chromatography. Yield: 0.423 g (45%). Anal. Calcd for C₃₃H₅₄FeN₂NiO₂P₂S₂: C, 52.75; H, 7.24; N, 3.73. Found: C, 52.34; H, 7.59; N, 3.99.

Data for cis-CO/trans-CN Isomer. IR (CH₂Cl₂, cm⁻¹): ν_{CN} = 2113, 2090, ν_{CO} = 2045, 1995. ³¹P NMR (CD₂Cl₂): δ 66.3 (s).

Dats for cis-CO/cis-CN Isomer. IR (CH₂Cl₂, cm⁻¹): ν_{CN} = 2120, ν_{CO} = 2033, 1982. ³¹P NMR (CD₂Cl₂): δ 67.8, 66.5 (AB quartet, J_{PP} = 33 Hz).

(CO)₂(CNBAr^F₃)₂Fe(pdt)Ni(dppe), 1(BAr^F₃)₂. A solution of (CO)₂(CN)₂Fe(pdt)Ni(dppe) (290 mg, 0.4 mmol) in 10 mL of CH₂Cl₂ was treated with a solution of BAr^F₃ (410 mg, 0.8 mmol) in 30 mL of CH₂Cl₂ dropwise. The reaction caused a change in color from a red to an orange solution. The reaction solution was concentrated to 20 mL and layered with 100 mL of pentane followed by cooling to –30 °C. Yield: 570 mg (82%). Crystals suitable for X-ray diffraction were grown from a concentrated THF solution of 1(BAr^F₃)₂ layered with pentane and cooled at –30 °C. IR (CH₂Cl₂, cm⁻¹): ν_{CN} = 2194, 2166, ν_{CO} = 2088, 2050. ³¹P NMR (CD₂Cl₂): δ 56.4 (s). ¹⁹F NMR (CD₂Cl₂): δ –133.7 (d, o-F), –135.1 (d, o-F), –159.2 (t, p-F), –159.4 (t, p-F), –165.0 (dt, m-F), –165.6 (dt, m-F). Anal. Calcd for C₆₉H₃₀B₂F₃₀FeN₂NiO₂P₂S₂: C, 47.32; H, 1.73; N, 1.60. Found: C, 47.24; H, 1.64; N, 1.52.

(CO)₂(CNBAr^F₃)₂Fe(pdt)Ni(dcpe), 2(BAr^F₃)₂. Analogously to the preparation of 1(BAr^F₃)₂, a solution of 2 (0.144 g, 0.0192 mmol) in CH₂Cl₂ (5 mL) was treated with a solution of BAr^F₃ (0.196 g, 0.0383 mmol), resulting in a color change from red to orange. The solvent was removed under vacuum, redissolved in THF, and crystallized by the addition of pentane followed by cooling to –30 °C. Yield: 0.253 g (74%).

Data for cis-CO/trans-CN Isomer. IR (CH₂Cl₂, cm⁻¹): ν_{CN} = 2190, 2149, ν_{CO} = 2085, 2046. ³¹P NMR (CD₂Cl₂): δ 69.8 (s). ¹⁹F NMR (CD₂Cl₂): –133.8 (d, o-F), –134.2 (d, o-F), –159.4 (t, p-F), –160.6 (t, p-F), –165.3 (t, m-F), –166.4 (t, m-F).

Data for cis-CO/cis-CN Isomer. IR (CH₂Cl₂, cm⁻¹): ν_{CN} = 2210, ν_{CO} = 2068, 2030. ³¹P NMR (CD₂Cl₂): δ 70.2, 69.5 (AB quartet, J_{PP} = 30 Hz). ¹⁹F NMR (CD₂Cl₂): –133.1 (d, o-F), –134.9 (o-F), –158.7 (t, p-F), –159.3 (t, p-F), –165.0 (t, m-F), –165.5 (t, m-F).

Et₄N[(CO)(CNBAr^F₃)₂Fe(H)(pdt)Ni(dppe)], Et₄N[H3(BAr^F₃)₂]. In a thick-walled glass pressure tube, a solution of 1(BAr^F₃)₂ (150 mg, 0.0857 mmol) in CH₂Cl₂ (10 mL) was frozen by inserting the tube into liquid nitrogen. Under a flow of Ar, a buffer layer of CH₂Cl₂ (5 mL) was frozen on top of the frozen solution of 1(BAr^F₃)₂. A solution of Me₃NO (7.7 mg, 0.103 mmol) in CH₂Cl₂ (2 mL) was frozen on top of the buffer layer. The head space was evacuated and refilled with 40 psig of H₂ followed by thawing of the frozen solution. After the mixture was stirred for 2 h, the solvent was removed under vacuum, and the residue was extracted into Et₂O. The extract was filtered through Celite and analyzed by ¹⁹F NMR spectroscopy, which showed 60% of signals corresponded to product. A solution of this sample in 10 mL of CH₂Cl₂ was stirred with excess Et₄NCl (142 mg, 0.857 mmol). The solvent was removed under vacuum, and the product was extracted into 10 mL of THF, which was then filtered through Celite and evaporated. The solid was dissolved in a minimal amount of THF and loaded onto a column of neutral alumina (Brockmann Level IV) packed with THF. A red band eluted with THF and was discarded. The remaining brown band was eluted off the column using CH₂Cl₂. The solution was concentrated to 5 mL, layered with 20 mL of pentane, and cooled to –30 °C yielding red crystals (44 mg, 28%). IR (CH₂Cl₂, cm⁻¹): ν_{CN} = 2162, 2137, ν_{CO} = 1963. ¹H NMR (CD₂Cl₂): δ –7.05 (t, J_{HP} = 5.2 Hz). ³¹P{¹H} NMR

(CD₂Cl₂): δ -66.6 (s). ¹⁹F NMR (CD₂Cl₂): δ -134.4 (o-F), -162.5, -162.9 (t, p-F), -167.4, -167.6 (t, m-F). Anal. Calcd for C₇H₅B₂F₃₀FeN₃NiOP₂S₂·0.3CH₂Cl₂: C, 48.83; H, 2.77; N, 2.30. Found: C, 48.81; H, 2.43; N, 2.24. Use of *N*-methylmorpholine-*N*-oxide in place of Me₃NO favored the b/b isomer. Et₄N[H₃(BAR^F₃)₂] was prepared from 1(BAR^F₃)₂ and Me₃NO using Et₄NBH₄ as the hydride source (see the Supporting Information).

Et₄N[(CO)(CNBAR^F₃)₂Fe(H)(pdt)Ni(dcpe)], Et₄N[H₄(BAR^F₃)₂]. This compound was prepared in a manner and yield similar to the preparation of Et₄N[H₃(BAR^F₃)₂]. IR (CH₂Cl₂, cm⁻¹): ν_{CN} = 2158, 2132, ν_{CO} = 1952. ¹H NMR (CD₂Cl₂): δ -6.56 (t, *J*_{HP} = 3 Hz). ³¹P{¹H} NMR (CD₂Cl₂): δ -85.1 (s). ¹⁹F NMR (CD₂Cl₂): δ -134.3 (d, o-F), -162.5, -163.0 (t, p-F), -167.3, -167.8 (t, m-F). Anal. Calcd for C₇H₅B₂F₃₀FeN₃NiOP₂S₂: C, 48.58; H, 4.02; N, 2.24. Found: C, 48.83; H, 4.00; N, 2.35.

Et₄N[(CO)(CNBAR^F₃)₂Fe(Cl)(pdt)Ni(dppe)], Et₄N[Cl₃(BAR^F₃)₂]. A solution of Et₄N[H₃(BAR^F₃)₂] (10 mg, 0.0054 mmol) in CD₂Cl₂ (0.7 mL) was treated with HCl (2 M in Et₂O, 6 μ L, 2.2 equiv, 0.012 mmol), resulting in that the solution turning slightly lighter in color. ¹H NMR confirmed the formation of H₂. ³¹P NMR displayed a major species (~60%) as an AB quartet at δ -51.5 and -48.6, and ¹⁹F NMR displayed signals for two inequivalent BAR^F₃⁻ environments, both consistent with an apical/basal arrangement of CNBAR^F₃⁻ ligands. Assignment of this major species as Et₄N[Cl₃(BAR^F₃)₂] was confirmed by independent synthesis of Et₄N[Cl₃(BAR^F₃)₂] from 1(BAR^F₃)₂ and Et₄NCl. Thus, a solution of 1(BAR^F₃)₂ (0.10 g, 0.057 mmol) in CH₂Cl₂ (10 mL) was treated with a solution of Me₃NO (5.1 mg, 0.069 mmol) in CH₂Cl₂ (1 mL) followed by Et₄NCl (9.5 mg, 0.057 mmol) in CH₂Cl₂ (5 mL). After the solution was allowed to stir for 15 min, solvent was removed under vacuum. The crude solid was dissolved in a minimal amount of THF and loaded onto a column of neutral alumina (Brockmann Level IV) eluting THF. The first red band was discarded, and the remaining brown band was eluted with CH₂Cl₂. The solution was concentrated to 5 mL, layered with 20 mL of pentane, and cooled to -30 °C precipitating an oil. Upon storing under vacuum, the oil was converted to a solid (40 mg, 37%). IR (CH₂Cl₂, cm⁻¹): ν_{CN} = 2181, 2149, ν_{CO} = 1996. ³¹P{¹H} NMR (CD₂Cl₂): δ -51.5, -48.6 (AB quartet, *J*_{PP} = 29 Hz). ¹⁹F NMR (CD₂Cl₂): δ -134.1, -134.6 (d, o-F), -161.9, -162.4 (t, p-F), -167.0, -167.2 (t, m-F). Anal. Calcd for C₇H₅B₂ClF₃₀FeN₃NiOP₂S₂: C, 48.33; H, 2.67; N, 2.22. Found: C, 48.30; H, 2.43; N, 2.43.
