Keywords: Carbazates Phenanthridines Alkoxycarbonylation/cyclization

ABSTRACT

An iron-catalyzed synthesis of 6-carboxylated phenanthridines starting with readily prepared isocyanides and carbazates was developed. Reactions occurred via addition of alkoxycarbonyl radicals to the isocyanide group and subsequent intramolecular cyclization.

Phenanthridines are biologically important compounds by its widespread presence in natural products, drugs, or drug candidates.¹ Many phenanthridines show antibacterial, antitumoral, and cytotoxic activities.² They are also widely used in material science due to their significant optoelectronic properties.³ Therefore, it is highly desirable to develop novel methods for the synthesis of diversified phenanthridines. Isocyanides are isoelectronic with carbon monoxide, and thus isocyanides can also act as radical acceptors to form imidoyl radicals, which can undergo bimolecular addition or cyclization.⁴ A few studies have been focused on the addition of radicals to 2-isocyanobiphenyls followed by intramolecular cyclization to generate phenanthridines (Scheme 1). Radicals were limited within trifluoromethyl,⁵ carbonyl,⁶ alkyl,⁷ and phosphoryl⁸.

On the other hand, carboxylic esters are valuable commodity chemicals and useful synthetic building blocks.⁹ Using carbazates as the precursors of alkoxycarbonyl radicals, Taniguchi and Tian reported introducing alkoxycarbonyl groups to styrenes to obtain carboxylic esters.¹⁰ Very recently, Du and our group reported the iron-catalyzed arylalkoxycarbonylation of N-arylacrylamides with carbazates independently, and various oxindole-3-acetates were obtained in good yields.¹¹ In 2014, Zhou reported a reaction about

All rights reserved. photosensitizer-catalyzed and oxygen-oxidated hydrazines to radical followed cyclization with 2-isocyanobiphenyls.¹² It provided a general and practical method for the construction of 6substituted phenanthridines. But only one 6-carboxylated phenanthridine was mentioned with 56% yield after irradiation for 18 h. Considering the importance of esters, we reported an iron-catalyzed oxidative alkoxycarbonylation–cyclization of 2-isocyanobiphenyls with carbazates.^{13,14}

Initially, we started to optimize reaction conditions by employing 2-isocyano-5-methylbiphenyl (**1a**) and methyl carbazate (**2a**) as model substrates. Using TBHP (*tert*-butyl hydroperoxide 70 wt % in water) as oxidant and FeCl₂·4H₂O as catalyst, the desired product **3a** was isolated in 56% yield after stirring in ethyl acetate (Table 1, entry 1). Without a catalyst, only a trace of the product was observed. Based on our previous results that ligands can coordinate with iron salt and influence the oxidation process of

^b Reaction time is 24 h.

^c 0.04 mmol phen·H₂O was used.

^d 0.8 mmol **2a** was used.

carbazates, we studied the effect of ligands on this reaction. Exper-
imental results show that 1,10-phenanthroline is the best ligand
(entry 8 vs entries 3-7). It improved the yield significantly from
56% to 76% (entry 8 vs entry 1). After screening catalysts, we found
that other catalysts were less efficient than FeCl ₂ ·4H ₂ O (entries 9-
12 vs entry 8). Notably, this transformation could be catalyzed by
an iodide catalyst. Using <i>n</i> -Bu ₄ NI as the catalyst, an acceptable
yield (66%) was obtained after the extended reaction time
(entries 13 and 14). Yields were slightly decreased when lessening
the dosage of catalyst or ligand (entries 15 and 16). When 4 equiv
of 2a was added, the product 3a was isolated in 82% yield
(entry 17). The influence of solvents was also investigated. The
reaction in ethyl acetate provided better result than that in
methanol, acetonitrile, or 1,2-dichloroethane (entry 18 vs entries
19–20).
•

With optimal conditions in hand, we turned our attention to explore the substrate scope of this reaction. The results are summarized in Table 2. Substitutions on the benzene ring A did not affect this transformation significantly, and these 2-isocvanobiphenyls afforded the desired products 3a-i in good yields. Different functional groups including fluoro, chloro, methyl, nitro, methoxyl, and ester are tolerable during the reaction process. Different 2-isocyanobiphenyls bearing a substituent on the ring B were then examined. Most of them worked well providing 6-carboxylated phenanthridines (3j-p) in moderate to good yields. Isocyanobiphenyls bearing an ortho-substituent on the benzene ring B gave lower yields than those bearing a para-substituent (3q vs 3j; 3r vs 3l).¹⁵ When 3s bearing a meta-substitution on the benzene ring B was subjected to this reaction, two regioisomers (2.6:1) were isolated. Isocyanide with an anthracene ring instead of the benzene ring B is applicable

^a Reaction conditions: **1** (0.2 mmol), FeCl₂-4H₂O (0.02 mmol), phen-H₂O (0.08 mmol), TBHP (1.0 mmol) in ethyl acetate (2 mL). After stirring well at 80 °C, **2** (0.8 mmol) was added in portions over 20 min, and the reaction was exposed to air for 4 h at the same temperature.

^b0.8 mmol phenyl hydrazine was used.

^c0.8 mmol acetyl hydrazine was used.

in this transformation with good yield (3t). Next, different carbazates were tested, and the reactions of ethyl, propyl, and phenyl carbazates with **1a** gave the corresponding products **3u**–**w** in moderate yields. Lastly, other accessible hydrazo compounds were tested in this transformation respectively. Only lower yields were obtained using phenyl hydrazine or acetyl hydrazine as the reactant (**3x**, **3y**).

When 5 equiv of TEMPO was added, the reaction did not provide the product, but gave the trapped product **4** in 60% yield. The result suggested that an alkoxycarbonyl radical was generated in this reaction (Scheme 2).

On the basis of the above experimental result and previous relevant mechanistic studies, a probable mechanistic explanation for this transformation is shown in Scheme 3. In the presence of Fe²⁺ and TBHP, diazene **A** is generated after successive oxidations of carbazate **2a**. Diazene **A** further loses a proton to give radical intermediate **B**, which releases molecular nitrogen to give alkoxycarbonyl radical **C**. The addition of **C** to isocyanide **1b** generates the imidoyl radical **D**, which next cyclizes to arene to form cyclohexadienyl radical **E**. Finally, radical E gives product **3b** via a protoncoupled electron transfer process with TBHP.

In conclusion, we disclosed a novel method for the synthesis of 6-carboxylated phenanthridines (as well as 6-phenyl and 6-acetyl phenanthridines) starting with readily prepared 2-isocyan-obiphenyls and commercially available carbazates. For this cas-cade reaction, cheap and convenient FeCl₂·4H₂O and TBHP were used. In addition, this reaction tolerates a variety of functional groups and shows promising potential for pharmaceutical applications.
