Abstract

An efficient green approach for the synthesis of *N*-cyclohexyl-3-aryl-quinoxaline-2-amine derivatives, via a three-component one-pot condensation reaction of *o*-phenylenediamine, aromatic aldehydes and cyclohexyl isocyanide in the presence of perlite-SO₃H nanoparticles (diameter/thickness of platelets < 100 nm) under ultrasound irradiation has been demonstrated. The present method offers advantages such as shorter reaction time, easy work-up, excellent yields, recovery and reusability of catalyst. In addition, the methodology has been prosperous in getting the green chemistry purposes such as natural catalyst, using ultrasound irradiation instead of conventional heating and stirring, and a non-hazardous products in the thus combining the features of both economic and environmental advantages.

Keywords *N*-Cyclohexyl-3-aryl-quinoxaline-2-amine · Perlite-SO₃H nanoparticles · Multicomponent reaction · Ultrasound irradiation

Introduction

During the past decade, isocyanide-based multicomponent reactions (IMCRs) achieved important concern within the scientific association as an effective, appropriate, time-saving, and atom-economical procedure to quickly produce chemical variety. IMCRs are quickly done using readily accessible starting materials and sustain a diversity range of functional groups. Alteration and following transformations prepare achievement to a justly great number of unique structures that would otherwise need prolix preparations [1–6]. Therewith, IMCRs have been extensively used in the pharmaceutical industry [7–9].

Quinoxaline derivatives are a usual incidence in plenty pharmacological active materials of natural or synthetic sources [10–12]. Many recognized antibiotics containing echinomycin, actinomycin, triostin A and leromycin have

the basic frame (Fig. 1) [13, 14]. The quinoxaline ring is also a constituent of many biologically and pharmacologically active compounds such as anthelmintics, fungicides, insecticides and herbicides [15, 16]. Quinoxaline derivatives have gained usage in dyes [17], electron luminescent substances [18], organic semiconductors [19], chemically controllable switches [20], as building blocks for the synthesis of anion receptors [21], cavitands [22], dehydroannulenes [23], DNA unzipping agents [24], and also minister as effective strict subunits in macrocyclic receiver or in molecular diagnosis [25, 26].

The usage of heterogeneous catalysts [27–30] has gained significant gravity in organic synthesis because of their facility of operation, elevated reaction rates, greater selectivity, easy work-up, and recoverability of catalysts. Between the different heterogeneous catalysts, exclusively, nano-perlite has advantages of eco friendly, low cost, ease of preparation and catalyst recycling [31]. Perlite is an amorphous volcanic glass that has a relatively high water value, typically formed by the hydration of obsidian. Because of its low density and relatively low price, many commercial applications for perlite have developed. In the construction and manufacturing fields, it is used in lightweight plasters and mortars, insulation and ceiling tiles. There are few reports about using perlite as suitable support for catalytic applications [31–35].

Ultrasound irradiation is well known to speed up chemical reactions [36, 37]. This is due to the event of acoustic cavitation, that is, the formation, development and crash of micrometrical bubbles, formed by the propagation of a pressure wave through a liquid. The crashes are quasiadiabatic processes, resulting in the production of high temperatures and pressures in the nanosecond time size, attended by sonoluminescence and mechanical effects. These effects can be applied to speed up chemical reactions, decreasing the reaction time and optimizing the profit–charge relevance. Moreover, this energetic flow can help to push forward both desirable and undesirable chemical reactions [36]. Therefore, the yields received with ultrasound-assisted reactions are various than those received under the similar conditions with classical synthetic methods [37].

As part of our continuing interest to develop the new ultrasound-promoted isocyanide-based multicomponent reactions [38–40], herein, we wish to report a green, effective and suitable method for the synthesis of *N*-cyclohexyl-3-aryl-quinoxaline-2-amine derivatives **4** using perlite-SO₃H nanoparticles as catalyst through one-pot condensation reaction of *o*-phenylenediamine **1**, aromatic aldehydes **2** and cyclohexyl isocyanide **3** (Scheme 1). We think that our work is in good agreement with the principles of green chemistry [41–44] such as inhibition of the formation of waste materials, having very high atom economy, eschewing of hazardous products, modeling safer products, using natural volcanic rock as catalyst, energy economy with operating reaction under ultrasonic irradiation and elimination of chemical stages with one-pot reaction.

Experimental

General

All reagents were purchased from Merck (Germany) and Fluka (Switzerland) and used without further purification. Infrared spectra were recorded on a Jasco 6300 FTIR spectrometer. Melting points were measured on an Electrothermal 9100 apparatus and are uncorrected. Sonication was performed in a Bandelin SONOPULS ultrasonic homogenizers

(made in Germany) with 20 kHz processing frequency, a nominal power 250 W and uniform sonic waves.

Preparation of perlite NPs

Perlite NPs were prepared from perlite mineral powder according to the preparation of silica nanoparticles from organic laboratory waste of silica gel HF₂₅₄ method [45]. The morphology and grain size of the perlite NPs was investigated by SEM and XRD (Figs. 1, 2, 3).

Preparation of perlite-SO₃H NPs

A 250-mL suction flask was equipped with a constant pressure dropping funnel containing chlorosulfonic acid (11.6 g, 0.1 mol) and a gas inlet tube for conducting HCl gas over an adsorbing solution, i.e., H₂O. Then 30.0 g of nanoperlite was charged in to the flask. Chlorosulfonic acid was added

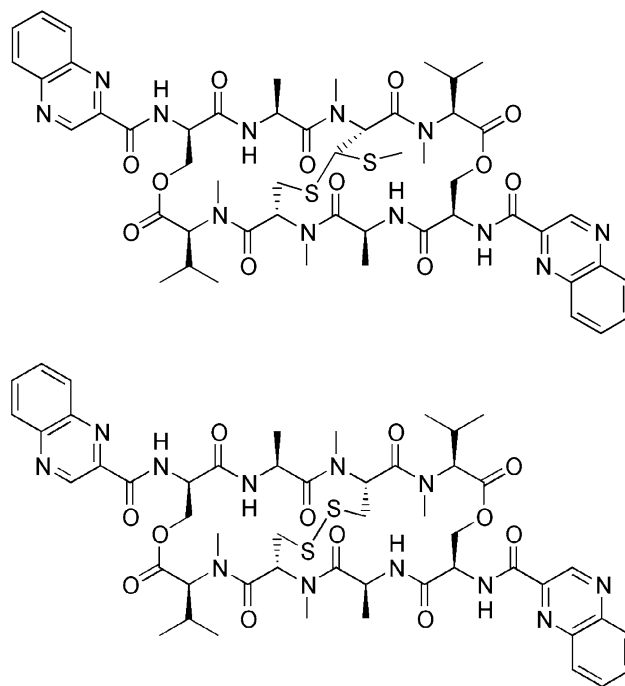

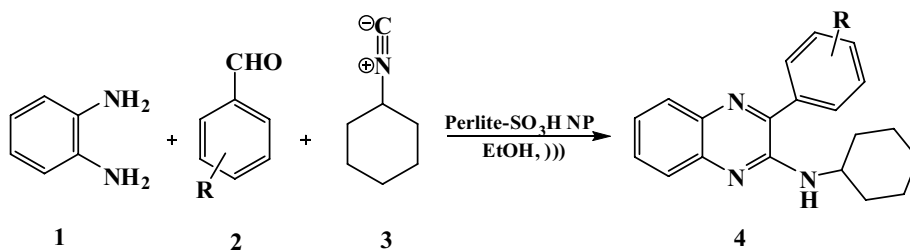

Fig. 1 Echinomycin (top) and triostin A (down) [13, 14]

Scheme 1 Synthesis of *N*-cyclohexyl-3-aryl-quinoxaline-2-amine derivatives **4a-i**

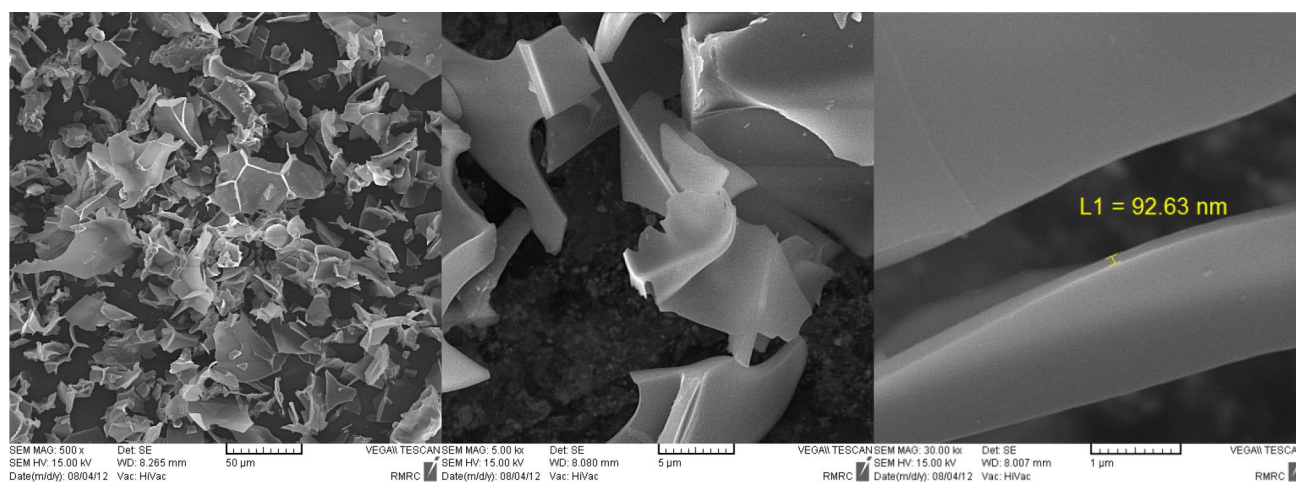

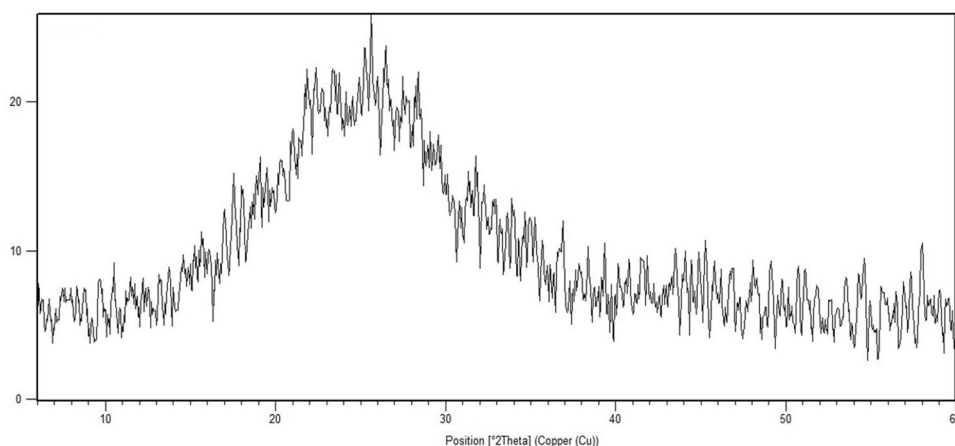

Fig. 2 SEM of the synthesized perlite nanoparticles

Fig. 3 X-ray diffraction pattern of the prepared perlite nanoparticles

drop wise over a period of 30 min at room temperature. HCl gas evolved from the reaction vessel immediately. After the addition was complete, the mixture was shaken for 30 min. Perlite-SO₃H was obtained as a white solid. The SEM image of the synthesized perlite-SO₃H nanoparticles has been showed in Fig. 4.

Acid strength measurement

Color test was done by moving 0.1 g of dried, powdered solid perlite-SO₃H NPs to a test tube, adding a 0.1% solution of methyl red in toluene as an indicator (three drops). From the color changing to red, it was easy to decide that the solid perlite-SO₃H NPs was acidic [46].

Acid amount determination

The quantity of acid sites on perlite-SO₃H NPs can be evaluated by amine titration directly after determination of acid strength by mentioned method [45]. The method includes

titration of the sample suspended in toluene with *n*-butylamine, using an indicator. The 0.1 N *n*-butylamine solution was provided by weighing 1.0 mL of *n*-butylamine in a 100-mL volumetric flask and making up the volume using dried toluene. Then, 0.2 g of dried perlite-SO₃H sample was transferred to a 50-mL Erlenmeyer flask. 9 mL of dry toluene and 3 mL of indicator solution in toluene were added to the sample suspension. Then, enough 0.1 N *n*-butylamine in toluene was added from a 2-mL burette to the sample so as to bracket the expected titer by the appropriate number of millimoles of *n*-butylamine per gram of perlite-SO₃H sample. The tightly capped sample was then equilibrated in a rotator at least for 4 h at room temperature. The titration was then continued using smaller stepwise increases in *n*-butylamine content until the end point.

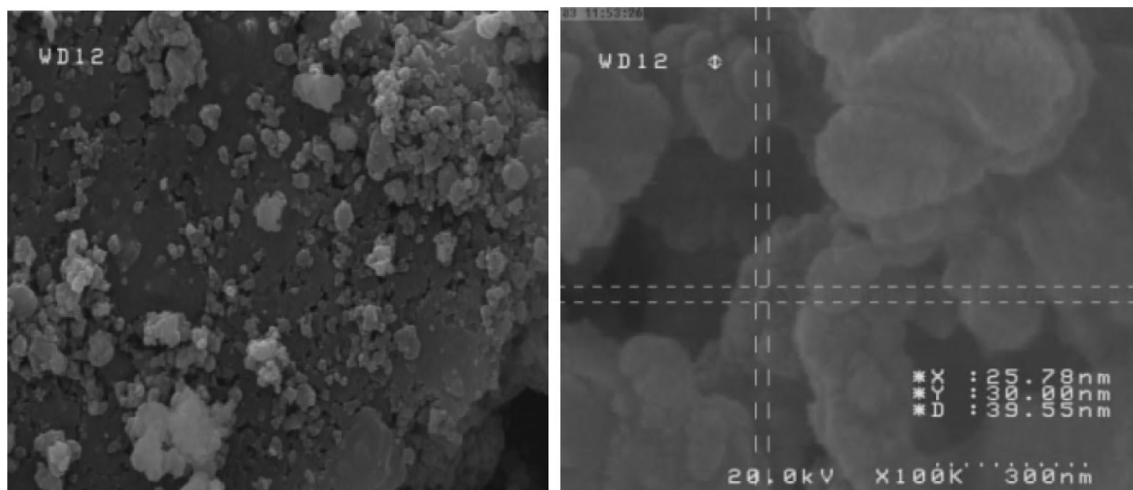

Fig. 4 The SEM image of the prepared perlite-SO₃H nanoparticles

General procedure for the one-pot synthesis of *N*-cyclohexyl-3-phenyl-quinoxaline-2-amines

To a mixture of *o*-phenylenediamine **1** (1 mmol), benzaldehyde **2a** (1 mmol), and cyclohexyl isocyanide **3** (1 mmol) in EtOH (10 mL), a catalytic amount of perlite-SO₃H (100 mg) was added and the mixture was irradiated under an ultrasonic processor at 150 W. The improvement of the reaction was monitored by TLC (ethyl acetate–hexane 1:3). After completion of the reaction, the resulting solid (catalyst) was separated by simple filtration and EtOH was removed and the reaction mixture was diluted with water (15 mL), and CH₂Cl₂ (15 mL) was added. The organic layer was separated and dried over MgSO₄. The solvent was evaporated under reduced pressure, and the product was obtained without any further purification.

Results and discussion

The amount of acid in the perlite-SO₃H NPs samples was investigated. It can be seen that the amount of acidity was observed in the case of perlite-SO₃H NPs as 2.46 mmole/g.

To get appropriate conditions for the synthesis of *N*-cyclohexyl-3-aryl-quinoxaline-2-amine (**4a–i**), different reaction conditions have been studied in the reaction of *o*-phenylenediamine **1**, benzaldehyde **2a** and cyclohexyl isocyanide **3** as a model reaction.

Effects of the catalyst under ultrasound irradiation

In a primary study, for examination of the amount of catalyst in this reaction, *o*-phenylenediamine **1**, benzaldehyde **2a** and

cyclohexyl isocyanide **3** were first reacted in EtOH (10 mL) for 40 min under ultrasound irradiation in the presence 0, 10, 20, 50, 100 and 200 mg of perlite-SO₃H nanoparticles separately. The best results were taken using 100 mg of catalyst (yield = 94%). Using lower amounts of catalyst resulted in lower yields, while higher amounts of catalyst did not affect the reaction times and yields and in the absence of catalyst, the yield of the product was found to be very low [33] (Table 1).

^aIsolated yields

Effects of the solvents under ultrasound irradiation

Here, we have varied the solvents condition such as water, methanol, acetonitrile, THF, dioxane and ethanol, the observation showed that the reaction using EtOH as solvent gave the best result, which gave the products not only in good yield but also with higher reaction rates (94% yield in 40 min) (Table 2, entry 6). Acetonitrile afforded moderate yields of desired products but took comparatively longer reaction time (Table 2, entry 3).

Effects of the ultrasound power

By enhancing the irradiation power from 50 to 150 W, the reaction time of **4a** reduced from 60 to 40 min and the yield increased from 52 to 94%. The reaction time and yield of **4a** did not shift from 150 to 200 W, thus, 150W of ultrasonic irradiation was enough to push the reaction forward. The best yield for **4a** was gained by ultrasonic irradiation for 40 min 150 W (Tables 3, 4) [39, 40].

Scheme 2 Proposed mechanism for the formation of *N*-cyclohexyl-3-aryl-quinoxaline-2-amine derivatives **4a-i**

Reusability of catalyst

Next, we investigated the reusability and recycling of perlite-SO₃H nanoparticles. At first, we put *o*-phenylenediamine **1** (1 mmol), benzaldehyde **2a** (1 mmol), cyclohexyl isocyanide **3** (1 mmol) and perlite-SO₃H NPs in EtOH (10 mL) as solvent at 150 W under sonication. When the reaction was completed (monitored by TLC), the resulting solid (catalyst) was separated by simple filtration and recovered perlite-SO₃H was reused in subsequent reactions without significant decrease in activity even after five runs (Table 5).

The feasible mechanism for the formation of product **4** is shown in Scheme 2. Product **4** is formed by the primary formation of minimum intermediate **A** from diamine **1** and aldehyde **2**. Intermediate **B** was made by the nucleophilic attack of isocyanide **3** to the iminium intermediate **A** and next by an intramolecular nucleophilic attack of NH₂ group to the nitrile moiety to yield intermediate **C**. Imine-enamine tautomerization of intermediate **C** and then catalytic dehydrogenation leads to the formation*** of product **4**.

Conclusion

In summary, we have extended a new, efficient and environment friendly one-pot three-component method for the synthesis of *N*-cyclohexyl-3-aryl-quinoxaline-2-amine derivatives under ultrasound irradiation in excellent isolated yields using EtOH as an almost non-hazardous, inexpensive and readily available solvent. The various substituents (electron-donating and electron-withdrawing) on each component of the coupling partner were well tolerated. The combination of the relatively fast reaction times, simple work-up methods and the aspects stated above mean that the methodology can be operated in a combi-chem mode to produce libraries organizing a various array of *N*-cyclohexyl-3-aryl-quinoxaline-2-amine derivatives.
