# Just Accepted

"Just Accepted" manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides "Just Accepted" as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. "Just Accepted" manuscripts appear in full in PDF format accompanied by an HTML abstract. "Just Accepted" manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). "Just Accepted" is an optional service offered to authors. Therefore, the "Just Accepted" Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the "Just Accepted" Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these "Just Accepted" manuscripts.

## ABSTRACT

Condensation of oximes with boronic acids  $RB(OH)_2$  or  $B(OH)_3$  affords remarkably stable 2,4,10-trioxa-1,5,7-triaza-3-boroadamantanes via an unprecedented multi-component process. The mechanism involves the reversible generation of unstable oxime cyclotrimers, which are readily intercepted by boronic acids.

#### INTRODUCTION

Adamantane derivatives find numerous applications in medicine, material sciences, as well as in the rational design of functional molecules and nanosystems.<sup>1</sup> Substitution of carbon atoms for heteroatoms provides vast opportunities for tuning adamatane properties and thus creation of substances and materials with predefined characteristics.<sup>2</sup> Thus, incorporation of heteroatoms such as nitrogen, oxygen or boron in adamantane cage results in a significant enhancement of pharmacological activity that led to development of highly potent heteroadamantane-based antiviral drugs.<sup>2a</sup> Some other staggering applications of heteroadamantanes are known. Polyazaadamantanes are used as precursors of high-energy materials<sup>2b</sup> and biodegradable polymers.<sup>2c</sup> Diamondoid molecules doped with oxygen atoms exhibit unusual electronic properties.<sup>2d</sup> Incorporation of boron and nitrogen atoms in the diamond structure produces a superhard and chemically inert material ("heterodiamond") with improved characteristics compared to diamond itself.<sup>2e</sup>

Owing to a significant progress in the synthesis of cage systems in 1960–1980s heteroadamantanes of various structures became available.<sup>3</sup> However, not any combination of heteroatoms in the adamantane skeleton leads to a stable cage structure.<sup>4</sup> The reasons of extreme stability of some heteroadamantanes and lability of other ones are still not completely understood being probably a superposition of various factors such as stereoelectronic effects, 3D aromacity, lone electron pair repulsion, electrostatic interactions, etc.<sup>4</sup> In this context, basic studies of structure, stability and reactivity of heterodiamondoid molecules are of high scientific interest.<sup>4,5</sup>

Unfortunately, traditional approaches to the construction of cage compounds seem to have exhausted themselves, and thus many challenging heteroadamantane structures still remain inaccessible.<sup>4</sup> Among them are 2,4,10-trioxa-1,5,7-triaza-3-heteroadamantanes (Scheme 1) none of which are known in literature. Quantum-chemical calculations at G4 level of theory predict thermodynamic stability of these heterocage systems over the corresponding isomeric orthoesters<sup>6</sup> (R-E(O-N=CH<sub>2</sub>)<sub>3</sub>) in case atom E is boron, carbon, phosphorous and some other p-elements. In the present work, the synthesis of 2,4,10-trioxa-1,5,7-triaza-3-boroadamantanes **1** as the first representatives of this unusual class of heteroadamantanes is reported.

Scheme 1. Suggested approach to the synthesis of heteroadamantanes 1.

We assumed that the assembly of heteroadamantanes **1** can be achieved by a multicomponent condensation of three oxime molecules with a boronic acid involving the formation of three boron-oxygen bonds and cyclotrimerization of oxime groups (Scheme 1). This previously unknown transformation does not have any close analogy in the chemistry of oximes and resembles the one-pot multi-component synthesis of methenamine from six molecules of formaldehyde and ammonia.<sup>7</sup>

#### **RESULTS AND DISCUSSION**

In our preliminary studies, phenylboronic acid was treated with an excess of formaldoxime generated *in situ* from formaldehyde and hydroxylamine in aqueous methanol (Scheme 2). We were pleased to find that the desired adamantane **1a** did form in moderate yield. However, product **1a** proved to be a labile compound slowly decomposing in solution (DMSO-d<sub>6</sub>, see. Supporting information) forming formaldoxime and an indecipherable product mixture. Based on quantum-chemical calculations we reasoned, that the presence of a proton on the nitrogen atom in product **1a** may be the course of the instability of 2,4,10-trioxa-1,5,7-triaza-3-boroadamantane cage. Indeed the adduct of 3-pyridinylboronic acid with formaldehyde oxime

(product **1b** in Scheme 2) proved to be more stable and formed in higher yield, probably, because the proton is localized preferably on the nitrogen atom of pyridine ring (Scheme 2).

Scheme 2. Interaction of formaldoxime with phenyl- and 3-pyridinylboronic acids.

In a similar fashion reaction of formaldehyde oxime with PhB(OH)<sub>2</sub> in presence of  $K_2CO_3$  furnished potassium salt of 2,4,10-trioxa-1,5,7-triaza-3-boroadamantane **1c** (entry 1, Table 1), for which X-Ray analysis was performed.<sup>8</sup> Product **1c** is stable on air up to 250°C and unlike **1a** does not undergo any noticeable decomposition upon storage in DMSO-d<sub>6</sub> solution within at least two weeks. Treatment of salt **1c** with an excess of HCl results in liberation of phenylboronic acid (73% yield) demonstrating that protonation leads to decomposition of 2,4,10-trioxa-1,5,7-triaza-3-boroadamantane structure.

Using this protocol several stable potassium salts of heteroadamantanes 1c-h containing various substituents at boron atom were obtained (entries 1–6, Table 1). Importantly, B(OH)<sub>3</sub> and B(OCH<sub>3</sub>)<sub>3</sub> also successfully entered the condensation with formaldehyde, hydroxylamine and K<sub>2</sub>CO<sub>3</sub> to yield potassium salt of adamantanes 1g and 1h in 86% and 85% yields, respectively (entries 5 and 6, Table 1).

Condensation of acetaldehyde oxime with phenylboronic acid in presence of  $K_2CO_3$  under solvent-free conditions afforded potassium salt **1i** in 73% yield as a mixture of diastereomers *eq,eq,eq-***1i** and *eq,eq,ax-***1i** in 2.0 : 1.0 ratio (entry 7, Table 1). Reaction with propionaldehyde oxime under same conditions was less smooth and the desired adamantane salt **1j** was formed in 10% yield (entry 8, Table 1). In case of a more bulky isobutyraldehyde oxime (Table 1, entry 9)

## The Journal of Organic Chemistry

the corresponding adamantane **1k** was detected only in trace amounts by ESI-HRMS. Benzaldehyde and acetone oximes did not react with phenylboronic acid (entries 10,11, Table 1).

n.r. – no reaction observed within 24 h. <sup>*a*</sup> Yields calculated on RB(OH)<sub>2</sub>. <sup>*b*</sup> B(OCH<sub>3</sub>)<sub>3</sub> was used. <sup>*c*</sup> n.s. – no solvent, 5 equiv. of H<sub>2</sub>O were added. <sup>*d*</sup> Eq and ax correspond to positions of substituents R<sup>2</sup> in triazine ring. <sup>*e*</sup> d.r.  $eq,eq,eq-\mathbf{1i}/eq,eq,ax-\mathbf{1i} = 2.0 : 1.0$ . <sup>*f*</sup> Determined by <sup>1</sup>H NMR with internal standard. <sup>*g*</sup> Characterized in mixture with potassium phenylborate, d.r.  $eq,eq,eq-\mathbf{1j}/eq,eq,ax-\mathbf{1j} = 1.0 : 1.4$ .

 These results clearly demonstrate that the presence of substituents at the oxime group complicates the formation of products **1**. We supposed that the formation of heteroadamantane **1** could proceed easier if three oxime groups were tethered together. The only compounds of this type available to date are tris( $\beta$ -oximinoalkyl)amines **2** (Table 2).<sup>9</sup>

Consequently we studied the interaction of various symmetrically and unsymmetrically substituted tris-oximes 2a-j with boronic acids (Table 2). Most of tris-oximes 2 studied did react with PhB(OH)<sub>2</sub> to give in good to high yields stable diamantanes 3 containing 2,4,10-trioxa-1,5,7-triaza-3-boroadamantane fused with 1,4,6,10-tetraazaadamantane cage (entries 1–5,8,10, Table 2). Since basic tertiary nitrogen is present in tris-oximes 2 all reactions were performed without an external base.

The nature of substituents at oxime groups mainly influenced the time needed for a full conversion of reagents, i.e. more bulky tris-oximes **2** reacted slower (cf. entries 2–5, Table 2). The exceptions were tris-oximes **2f** bearing three phenyl groups (entry 6, Table 2), **2g** with three CO<sub>2</sub>Et substituents (entry 7, Table 2) and **2i** bearing two phenyl and one benzyl group (entry 9, Table 2). No conversion of these tris-oximes was observed. On the contrary, condensation of PhB(OH)<sub>2</sub> with tris-oxime **2h** possessing two phenyl groups and a hydrogen at the oxime groups produced the desired unsymmetrically substituted diamantane **3h** in moderate yield (entry 8, Table 2). Therefore, reaction of tris-oximes **2** with boronic acids proved to be much less sensitive to the substitution at oxime groups as compared to mono-oximes. In particular, aldoximes as well as ketoximes **2** bearing relatively bulky benzyl and phenyl groups afforded the corresponding diamantanes **3** efficiently.

Various boronic acids were well-tolerated in the reaction with tris-oximes **2** (entries 11-15, Table 2). In addition to PhB(OH)<sub>2</sub> diamantane adducts of tris-oxime **2b** with methyl-, cyclopropyl-, *trans*-styrylboronic acids as well as with B(OH)<sub>3</sub> were prepared in excellent yields (entries 11–14, Table 2). 1,4-Phenylenediboronic acid in reaction with two equivalents of tris-oxime **2b** selectively produced a 1 : 2 adduct **3o** in high yield (entry 15, Table 2).

Structures of diamantanes **3b** and **3n** were secured by single-crystal X-Ray analysis (Scheme 3).<sup>8</sup> Interestingly, in the crystal of **3n** the acidic proton is localized on nitrogen atom N(1) (form **A**), while in **3b** nitrogen N(2) is protonated (form **B**) (Scheme 3). In result, a considerable distortion of triazine ring is observed in **3b** due to the elongation of bonds C(4)–N(2) and C(5)–N(2) (by 0.02–0.04 Å) and shortening of bonds C(4)–N(3) and C(5)–N(4) (by 0.02–0.03 Å) as compared to analogous bonds in **3n**. Such distortion results from strong  $lp(N)\rightarrow\sigma^*_{C-N(2)}$  interactions in structure **B** leading to charge transfer from lone electron pairs of nitrogens N(3) and N(4) to the  $\sigma^*$  orbitals of C–N(2) bonds as confirmed by NBO analysis for **3b** (Supporting information). Furthermore, the presence of a positive charge on nitrogen N(2) in diamantane **3b** leads to the expected shortening of N(2)<sup>+</sup>–O(1) bond (by 0.03 Å) and elongation of B–O(1) bond (by 0.02–0.03 Å) as compared to the corresponding bonds with N(3) and N(4). It is likely, that there is equilibrium between zwitterionic forms **A** and **B** in solution leading to the observed widening of signals in NMR spectra in products **3**.

Scheme 3. Structures of diamantanes 3n and 3b. Methyl groups are omitted for clarity.

Two mechanisms can be proposed for the discovered condensation of oximes with boronic acids (Scheme 4). The first pathway involves oxime cyclotrimerization furnishing all-*cis*-1,3,5-

#### The Journal of Organic Chemistry

trihydroxy-hexahydro-1,3,5-triazines 4,<sup>10</sup> which serve as matrix for the assembly of adamantanes 1 in reaction with RB(OH)<sub>2</sub>. The second pathway starts with condensation of three oxime molecules with a boronic acid furnishing boronates 5, which then cyclize to adamantane 1. Both routes involve as a key stage the cyclotrimerization of C=N-O fragments, which is non-typical for oximes.

Calculated free energies of oxime cyclotrimerization in gas-phase:

<u>Intermolecular</u>	(3 oximes <del> 4</del> )	<u>Intramolecular</u> (tr	ris-oxime 2 <del>ح</del> 6)
Oxime	∆Gr <sup>o</sup> <sub>298,15K</sub> kcal mol <sup>-1</sup> (method)	Tris-oxime	∆Gr <sup>o</sup> <sub>298,15K</sub> kcal mol <sup>-1</sup> (method)
H₂C=NOH	+4.6 (G4)	2a	-3.8 (G4MP2)
CH3HC=NOH EtHC=NOH (CH3)2C=NOH	+7.6 (G4) +8.2 (G4MP2) +27.2 (G4MP2)	2b	-0.7 (G4MP2)

Scheme 4. Possible mechanisms for the formation of heteroadamantanes 1.

In our experiments we never observed the formation of open-chain oxime ethers **5** neither in methanol/H<sub>2</sub>O nor in toluene solutions. In those cases when adamantanes **1** or **3** were not formed the initial oximes and boronic acids remained unchanged (according to <sup>1</sup>H NMR, see Supporting Information). On the other hand, stable 1,3,5-trihydroxy-1,3,5-triazines  $4a \cdot HCl^{10}$  and 6b (prepared from  $2b^{9b}$ ) readily reacted with phenylboronic acid to give the corresponding adamantanes **3b** in quantitative yield (Scheme 5). Furthermore, strong correlation between

oxime cyclotrimerization and the formation of corresponding boradamantanes is observed: trisoximes 2f,g,i, which did not enter the intramolecular oxime cyclotrimerization,<sup>9b</sup> did not react with boronic acids (entries 6,7,9, Table 2). These data suggest that pathway (1) involving oxime trimers 4 or 6 as key intermediates is likely to be involved (Scheme 4). However, pathway (2) can not be completely ruled out as a competitive route considering that boronate 5 cyclization to heteroadamantane 1 should be thermodynamically favored according to G4 theory level calculations (see Scheme 1 and Supporting Information).

Scheme 5. Reaction of 1,3,5-trihydroxy-1,3,5-triazines 4a•HCl and 6b with PhB(OH)<sub>2</sub>.

Pathway (1) explains why the formation of heteroadamantanes **1** from substituted oximes is difficult (Table 1). Evidently, the reason is thermodynamic instability of oxime cyclotrimers **4**.<sup>9b,10</sup> In contrast to azomethines and carbonyl compounds,<sup>11</sup> the intermolecular cyclotrimerization of oximes has been reported only for formaldoxime.<sup>10</sup> The resulting trimer **4a** is a kinetic product and decomposes to a monomer and polymer.<sup>10</sup> Substitution at the oxime group hampers its cyclotrimerization both in inter- and intramolecular variant that is well-illustrated by high-level quantum-chemical calculations (see table in Scheme 4). Thus, we failed to observe cyclotrimerization of acetaldehyde oxime by <sup>1</sup>H NMR in a broad concentration range

#### The Journal of Organic Chemistry

 $(0.2 \div 10 \text{M in CDCl}_3)$  indicating that the equilibrium concentration of the corresponding trimer **2** is very low. Apparently, cyclotrimerization of simple aldoximes takes place only to a very small extent, however, the trimer **4** still can be intercepted by a boronic acid to give a stable heteroadamantane anion **1**. Therefore, reactions with boronic acids may serve as a convenient tool to study oxime cyclotrimerization process.

The suggested strategy for the synthesis of B,O,N-doped adamantanes may be useful in the construction of pH responsible boronate linear polymers, dendrimers and supramolecular systems.<sup>12</sup> 2,4,10-trioxa-1,5,7-triaza-3-boroadamantanes of type **1** and **3** represent interest as potential antiviral agents considering their structural similarity to bananins.<sup>2a,13</sup> Furthermore, boradamantane salts **1**, which are readily prepared by mixing RB(OH)<sub>2</sub> with formaldehyde, hydroxylamine and K<sub>2</sub>CO<sub>3</sub>, may be considered as convenient thermo- and air-stable forms of boronic acids. Interestingly, unlike other boronates,<sup>14</sup> adamantane **1c** proved to be unreactive in Suzuki-Miyaura (SM) coupling with 1-bromo-4-nitrobenzene and 1-bromo-4-methoxybenzene at ambient temperature. The formation of coupling product (4-nitrobiphenyl) was observed only at elevated temperatures and led to complete decomposition of heteroadamantane (Scheme 6).

Scheme 6. SM coupling with boradamantane 1c.

Similar behavior was recently reported by Kuno<sup>15</sup> for adamantane-like boronates derived from *scyllo*-inosytol, which thus was suggested as an effective protective group for arylboronic acids.<sup>14</sup> In this context, boradamantanes **1** may be considered as an alternative to *scyllo*-inosytol complexes of boronic acids. Further studies on application of 2,4,10-trioxa-1,5,7-triaza-3-

boroadamantanes 1 and 3 in other transition metal-catalyzed cross-coupling reactions are currently underway.

#### CONCLUSIONS

In summary, a straightforward synthesis of hitherto unknown 2,4,10-trioxa-1,5,7-triaza-3boroadamantanes and their fused derivatives has been achieved by an unprecedented multicomponent condensation of oximes with boronic acids. The discovered process involves uncommon cyclotrimerization of oximes to unstable 1,3,5-trihydroxy-1,3,5-triazaadamantanes, which react with boronic acids to give the desired heteroadamantanes.

#### **EXPERIMENTAL SECTION**

All reactions were performed in oven-dried (150°C) glassware. 1D and 2D NMR spectra were recorded at room temperature on a 300 MHz spectrometer with residual solvents peaks as an internal standard.<sup>16</sup> Chemical shifts in <sup>11</sup>B are given in relative to BF<sub>3</sub>•Et<sub>2</sub>O. Multiplicities are indicated by s (singlet), d (doublet), t (triplet), q (quartet), quint (quintet), m (multiplet), br (broad). *W* values correspond to full width at half maximum of signal in Hz. Peaks in FT-IR-spectra data are reported in cm<sup>-1</sup> with the following relative intensities: s (strong), m (medium), w (weak), br (broad), sh (shoulder). HRMS were measured on electrospray ionization (ESI) instrument with a time-of-flight (TOF) detector. Analytical thin-layer chromatography was performed on silica gel plates with QF-254. Visualization was accomplished with UV light and solution of ninhydrine/acetic acid in ethanol. CH<sub>3</sub>OH, EtOH and ethyl acetate were distilled without drying agents. All inorganic reagents and boronic acids were commercial grade and were used as received. Tris-oximes **2a,c,d,g**.<sup>9b</sup> **2b,e,f**.<sup>9a</sup> **2i j**<sup>9c</sup> and 1,4,6,10-tetraazaadamantane **6b**.<sup>9b</sup> were synthesized according to previously published protocols. Quantum-chemical calculations were performed with the Gaussian 09 program.

Synthesis of 3-Boro-2,4,10-trioxa-1,5,7-triazaadamantanes 1a-g. To a stirred solution of boronic acid or B(OH)<sub>3</sub> (1.0 mmol) in 1.8 mL of CH<sub>3</sub>OH (for 1a-f) or water (for 1g) at 0°C was added a 37% aqueous solution of formaldehyde (0.75 mL, 10 mmol) followed by a 50% aqueous solution of hydroxylamine (0.61 mL, 10 mmol). The mixture was stirred for 10 min at 0°C, warmed up to room temperature and stirred for 18 h followed by addition of potassium carbonate (69 mg, 0.5 mmol, for the synthesis of 1c-g). After stirring for additional 5 h the reaction mixture was diluted with water (5 mL) and the precipitate was centrifuged off and washed with water (5 mL) and CH<sub>3</sub>OH (5 mL) in centrifuge cups. Combined solutions were evaporated in vacuum at 45-50°C and the residue was dried in vacuum at 0.1 Torr until constant weight (unstable products 1a,b were dried at room temperature, products 1c-g were dried at 100°C).

Synthesis of 3-Boro-2,4,10-trioxa-1,5,7-triazaadamantane 1h. To a stirred solution of B(OCH<sub>3</sub>)<sub>3</sub> (0.112 mL, 1.0 mmol) in 1.8 mL of CH<sub>3</sub>OH at 0°C was added a 37% aqueous solution of formaldehyde (0.75 mL, 10 mmol) followed by a 50% aqueous solution of hydroxylamine (0.61 mL, 10 mmol). The mixture was stirred for 10 min at 0°C, warmed up to room temperature and stirred for 18 h followed by addition of potassium carbonate (69 mg, 0.5 mmol). After stirring for additional 5 h the reaction mixture was diluted with CH<sub>3</sub>OH (5 mL) and the precipitate was centrifuged off and washed with CH<sub>3</sub>OH (2×5 mL) in centrifuge cups. Combined solutions were evaporated in vacuum at 45-50°C to give a mixture of 1g and 1h (ratio 1.6 : 1.0). The residue was dissolved in CH<sub>3</sub>OH (10 mL) and refluxed for 1 h to convert 1g to 1h and evaporated in vacuum. The product was dried in vacuum at 0.1 Torr and 100°C (without melting). <sup>1</sup>H NMR (300 MHz, DMSO-d6):  $\sigma = 3.07$  (s, 3 H), 4.14 (d, J = 12.1 Hz, 3 H), 4.41 (d, J = 12.1 Hz, 3 H), <sup>13</sup>C NMR (75 MHz, DMSO-d6):  $\sigma = 47.9$ , 72.7. <sup>11</sup>B NMR: (96 MHz, DMSO-d6):  $\sigma =$ 

Synthesis of 3-Boro-2,4,10-trioxa-1,5,7-triazaadamantanes 1i,j. Phenylboronic acid (122 mg, 1.0 mmol), oxime (10 mmol) were placed in a vial, water (0.09 mL, 5.0 mmol) was added and the resulting slurry was stirred for 5 min followed by addition of potassium carbonate (69 mg, 0.5 mmol). After stirring for 24 h at room temperature the reaction mixture was diluted with  $Et_2O$  (3 mL) and water (3 mL). The organic layer was separated, the aqueous layer was washed with  $Et_2O$  (3 × 2 mL) and the combined organic extracts were washed with water (2 mL). The combined aqueous solutions were evaporated at in vacuum at 45-50°C and the residue was dried in vacuum at 0.1 Torr and 100°C until constant weight.

Synthesis of 3-Boro-2,4,10-trioxa-1,5,7-triazaadamantane 1c from formaldoxime trimer hydrochloride  $4a \bullet HCl$ . To a stirred solution of hydrochloride  $4a \bullet HCl$  (172 mg, 1.0 mmol) and phenylboronic acid (122 mg, 1.0 mmol) in CH<sub>3</sub>OH (7.5 mL) was stirred for 18 h. Then K<sub>2</sub>CO<sub>3</sub> (69 mg, 0.5 mmol) was added and the mixture was stirred for additional 5 h. The resulting mixture was filtered through syringe filter and evaporated in vacuum. The residue was dried in vacuum until constant weight to give 221 mg (85%) of boradamantane 1c as white solid.

**Synthesis of 3-Boro-2,4,10-trioxa-1,5,7-triazaadamantane 3b from adamantane 6b.** To a stirred solution of adamantane **6b** (115 mg, 0.5 mmol) in CH<sub>3</sub>OH (3.8 mL) was added phenylboronic acid (61 mg, 0.5 mmol). The solution was stirred at room temperature until full consumption of starting material (0.5 h, TLC control) and evaporated in vacuum. The residue was triturated with AcOEt and dried in vacuum (0.1 Torr and 100°C) until constant weight to give 155 mg (98%) of boroadamantane **3b** as a white solid.

**Decomposition of boradamantane salt 1c under acidic conditions.** To a solution of boradamantane salt **1c** (115 mg, 0.44 mmol) in 1 mL of water was added concentrated aqueous solution of HCl (36% in water, 0.2 mL). The mixture was kept for 1 h and then extracted with CHCl<sub>3</sub> (8×5 mL). Combined organic extracts were dried (Na<sub>2</sub>SO<sub>4</sub>) and evaporated in vacuum to give 39 mg (73%) of phenylboronic acid (Mp 212-214°C, lit. 214-219 °C (Alfa Aesar)).

SM coupling of boradamantane salt 1c with 1-bromo-4-nitrobenzene. To a solution of  $Pd(OAc)_2$  (2 mg, 0.009 mmol) in 0.6 mL of DMF/H<sub>2</sub>O mixture (5 : 1) was added boradamantane salt 1c (52 mg, 0.2 mmol) and 1-bromo-4-nitrobenzene (36 mg, 0.18 mmol) under argon atmosphere. The mixture was stirred at 100°C for 5 h. After cooling the organic products were extracted with Et<sub>2</sub>O (3×3 mL). Combined organic layers were washed with water, dried (MgSO<sub>4</sub>) and evaporated in vacuum. Flash-chromatography (pentane-Et<sub>2</sub>O = 10 : 1) of the residue provided 26 mg (71%) of 4-nitrobiphenyl (GC-MS) as white crystals (Mp 111-114°C, lit.<sup>19</sup> 112-114°C).

Synthesis of N-(2-{[2-(hydroxyimino)-2-phenylethyl][1-(hydroxyimino)propan-2-yl]amino}-1-phenylethylidene)hydroxylamine (2h) (synthesized according to procedure used for  $2i^{9c}$ ). To a stirred solution of N-(2-aminopropylidene)hydroxylamine<sup>9c</sup> (176 mg, 2.0 mmol) in 8 mL of dioxane was added a 1 M solution of 2,2,6,6-tetramethyl-4-(1-phenylethenyl)-3,5-dioxa-4-aza-2,6-disilaheptane<sup>20</sup> in dry CH<sub>2</sub>Cl<sub>2</sub> (4.4 mL, 4.4 mmol). After 24 h at room temperature 20 ml of CH<sub>3</sub>OH was added and the mixture was kept for additional 5 h with stirring. Then the mixture was evaporated in vacuum at 37 °C. The residue was preadsorbed on silica gel and purified by flash chromatography (silica gel; EtOAc–hexane, 1:1 then EtOAc and EtOAc–CH<sub>3</sub>OH, 3:1). The residue was triturated with CHCl<sub>3</sub> and dried in vacuum (0.1 Torr, room temperature) until constant weight to give 438 mg (61%) of oxime **2h** as a yellowish solid. Mixture of three isomers (ratio **2h'** : **2h'''** = **5**.2 : 3.8 : 1.0). <sup>1</sup>H NMR (300 MHz, DMSO-d6, HSQC, isomer **2h'**): 1.05 (d, J = 6.5 Hz, 3 H,  $CH_3$ ), 3.34 (m, 1 H, CH), 3.68 (d, J = 13.5 Hz, 2 H,  $CH_2$ ), 3.85 (d, J = 13.5, 3.4 Hz, 2 H,  $CH_2$ ), 7.11–7.46 (m, 11 H, 2 C<sub>6</sub>H<sub>5</sub> and N=CH), 10.69, 10.96 and 11.45 (3 s, 3 H, 3 NOH). <sup>1</sup>H NMR (300 MHz, DMSO-d6, HSQC, isomer **2h''**): 1.11 (d, J = 7.6 Hz, 3 H,  $CH_3$ ), 3.34 (m, 3 H, CH and  $CH_2$ ), 3.59 (d, J = 13.2 Hz, 2 H,  $CH_2$ ), 7.11–7.46 (m, 11 H, 2 C<sub>6</sub>H<sub>5</sub> and N=CH), 10.73, 10.85 and 11.50 (3 s, 3 H, 3 NOH). <sup>1</sup>H NMR (300 MHz, DMSO-d6, HSQC, isomer **2h'''**): 0.97 (d, J = 6.6 Hz, 3 H,  $CH_3$ ), 3.19 (m, 1 H, CH), 3.46 (s, 4 H,  $CH_2$ ), 6.72 (d, J = 5.9 Hz, 1 H, N=CH), 7.11–7.46 (m, 10 H, 2 C<sub>6</sub>H<sub>5</sub>), 10.64, 10.94 and 11.41 (3 s, 3 H, 3 NOH). <sup>13</sup>C NMR (75 MHz, DMSO-d6, HSQC, **2h'** and **2h''**): 11.8 and 12.0 ( $CH_3$ ), 42.8, 53.0, 53.2, 53.4, 53.9 (CH and  $CH_2$ ), 126.4, 127.4, 127.7, 127.8, 128.2, 128.3, 128.5 (o, m, p- $C_6$ H<sub>5</sub>), 135.5 (i- $C_6$ H<sub>5</sub>), 150.1 and 154.1 (C=N). <sup>13</sup>C NMR (75 MHz, DMSO-d6, HSQC, characteristic signals of **2h''''**): 152.8 (C=N). ESI-HRMS m/z: [M+H]<sup>+</sup> Calcd for C<sub>19</sub>H<sub>22</sub>N<sub>4</sub>O<sub>3</sub> 355.1765; Found 355.1758. [M+Na]<sup>+</sup> Calcd for C<sub>19</sub>H<sub>22</sub>N<sub>4</sub>O<sub>3</sub> 377.1584; Found 377.1576.

## SUPPORTING INFORMATION

Characterization data for all new compounds, NMR and GC-MS for known compounds, X-ray data, Cartesian coordinates, absolute energies for all optimized geometries and NBO analysis summary. This material is available free of charge via the Internet at http://pubs.acs.org.

### ACKNOWLEDGMENTS

The support from Russian Foundation for Basic Research (grant # 14-03-00933-a) and Russian President's Council for Grants (grant MK-5957.2015.3) is greatly acknowledged.
