ABSTRACT: The intramolecular bromoamination of *O*-allyl-*N*-tosyl-hydroxylamines results in the formation of isoxazolidines via selective 5-endo-tet cyclization. This process occurs *trans*-selectively in high yield and diastereoselectivity. The obtained R¹ bromo-isoxazolidines provide access to other useful building blocks, such as 2-azido-aminoalcohols, diaminoalcohols, and aziridines.

Electrophilic activation of unsaturated hydrocarbons bearing internal nucleophiles has been widely used for the preparation of different heterocycles in organic synthesis.¹ In this respect amines,² carbamates,³ amides,⁴ urea derivatives,⁵ imines,⁶ oximes,⁷ oxime ethers,⁸ hydrazines,⁹ hydroxamic acids,¹⁰ and hydroxylamines¹¹ have been utilized in such cyclization reactions with various electrophiles. This approach was successfully employed for the preparation of various pharmacologically active compounds and synthetic building blocks.¹²

Substituted isoxazolidines have been synthesized via 1,3dipolar cycloadditions of nitrones with alkenes¹³ or metalcatalyzed cyclization reactions¹⁴ and are important precursors to β -amino alcohols,¹⁵ β -amino ketones,¹⁶ β -amino acids,¹⁷ and 3-isoxazolidones.¹⁸ Studer¹⁹ and Togo²⁰ independently developed an *exo*-selective bromocyclization of *O*-homoallylhydroxylamine derivatives leading to bromo-isoxazolidines. However, isoxazolidines with a bromo-substituent on a stereogenic center have not been investigated in detail. Therefore, we were interested in the behavior of *O*-allyl-*N*tosyl-hydroxylamines toward electrophilic activation. Herein, we present the bromocyclization of *O*-allyl-*N*-tosyl-hydroxylamines, which proceeds to diastereomerically pure bromoisoxazolidines via 5-*endo-tet* ring closure.

RESULTS AND DISCUSSION

The *O*-allyl-*N*-tosyl-hydroxylamines were readily prepared by Mitsunobu reaction²¹ starting from allylic alcohols 1a-k using *N*-hydroxyphthalimide as nucleophile following a modified protocol by Saito.²² Subsequent hydrazinolysis of the *O*-allyl-*N*-phthalimido-hydroxylamines 2a-k and reprotection with *p*-TsCl gave the corresponding *O*-allyl-*N*-tosyl-hydroxylamines 3a-k (Scheme 1).

Initially, we screened different halonium sources and solvents for the intramolecular halocyclization of **3a** (Table 1). Utilizing brominating agents like N-bromosuccinimide (NBS), 1,3dibromo-5,5-dimethylhydantoin (DBDMH), bis(2,4,6trimethylpyridine)bromine(I) hexafluorophosphate $(Br^+(coll)_2PF_6^-)$, or *N*-bromoacetamide (NBA), bromo-isoxazolidine 4a was formed in complete diastereoselectivity and high yields (Table 1, entries 1–4). The formation of the fivemembered ring as well as the relative *trans*-configuration between the phenyl- and bromo-substituent were confirmed by X-ray analysis.²³

ŃН

N-Bromoacetamide in dichloromethane or in acetonitrile led to a comparable outcome (91% vs 88% yield, Table 1, entries 4 and 9). In contrast, employing toluene or THF as solvents drastically increased reaction time and lowered the yield of **4a** to 79 and 35%, respectively (entries 5 and 6). To our surprise, the use of *N*-chlorosuccinimide (NCS) and 1,3-dichloro-5,5dimethylhydantoin (DCDMH) did not lead to any observable reaction within 24 h (entries 10 and 11).

After optimal reaction conditions for the selective bromocyclization of O-allyl-N-tosyl-hydroxylamines were found, the scope of this reaction was investigated. As depicted in Table 2, trans-alkenes bearing aromatic substituents smoothly undergo diastereoselective (dr > 98:2) cyclization to the corresponding *trans*-aryl-bromo-isoxazolidines 4a, 4c, and 4d (Table 2, entries 1, 3, and 4). Thus, electron-rich aromatic systems can be employed without difficulty. In contrast, p-NO2-phenyl-substituted alkene 3e did not undergo cyclization, which is consistent with the assumption of an electrophilic attack of the double bond. Cyclization of substituted cis-styrene derivatives 3b and 3f (Table 2, entries 2 and 6) diastereoselectively led to the corresponding *cis*-arylbromo-isoxazolidines 4b and 4f, in yields of 83 and 65%, respectively. These cis-alkenes required longer reaction times, which can be rationalized by considering A^{1,3}-strain interactions.24

Treatment of 3c with NBA under optimized conditions afforded 4c as a single diastereomer exemplifying the influence of an existing stereocenter on the stereochemical outcome. The high selectivity may be explained by unfavorable steric interactions in one of the two assumed transition states as

shown in Scheme 2. Since all bromo-isoxazolidines 4a-d and 4f were obtained as single diastereomers, overall trans-addition by S_N2-attack of a bromonium intermediate is assumed. Besides styrene derivatives, we scrutinized the behavior of mono- and dialkyl substituted derivatives 3g-i. Bromocyclization of methylbutenyl- and trans-hexenyl derivatives 3g and 3h led to isoxazolidines 4g and 4h in 84 and 70% yield, respectively (Table 2, entries 7 and 8). In contrast, similar treatment of cishexenyl hydroxylamine 3i afforded a complex mixture of products (Table 2, entry 9). While rapid consumption of starting material upon addition of the brominating agent was observed, nucleophilic ring closure is presumably unfavored for steric reasons. Therefore, intermolecular nucleophile attack may dominate. Cyclohexenyl derivative 3j smoothly underwent diastereoselective cyclization to the corresponding bicycle 4j in 91% yield. The octahydrobenzo[c]isoxazole structure of 4j could be confirmed by X-ray analysis.²³ Surprisingly, treatment of the closely related cyclopentenyl derivate 3k with NBA gave a mixture of products from which only 4k could be isolated in a vield of 26%.

Focusing on the mechanism of the bromocyclization initial ¹H NMR studies revealed that 1.1 equiv NBA added to **3b** in CDCl₃ led to the disappearance of the NH-signal at 7.07 ppm accompanied by a highfield shift of the β -styrene proton from 5.78 ppm to 5.66 ppm. Concomitant formation of acetamide (CH₃CONH₂) was observed. After a while, bromo-isoxazolidine **4b** was formed, and at the same time, disappearance of the putative *N*-bromo-species was monitored (Scheme 3). In addition, treatment of *p*-NO₂-phenyl-substituted derivative **3e** with 1.0 equiv NBA in CDCl₃ provided *N*-brominated hydroxylamine derivative **5**, which does not undergo cyclization and could be isolated (Scheme 4).²⁵ Reaction of this intermediate with 3a cleanly led to isoxazolidine 4a with back-formation of alkene 3e within 15 min.

These observations suggest that in the first place an *N*bromo-species is formed, which then undergoes either intra- or intermolecular bromination of the double bond. Subsequent nucleophilic opening of the bromonium intermediate leads to the final product.

The bromo-isoxazolidines can be further transformed into various synthetic building blocks. Since direct nucleophilic displacement of the bromo-substituent of **4a** with azide sources such as TMSN₃/TBAF,²⁶ or NaN₃ in DMF was unsuccessful, the N–O bond was cleaved first (Scheme 5). Hydrogenation of **4a** in the presence of 10 mol % Pd/C as catalyst provided the corresponding bromo-aminoalcohol **6** in almost quantitative yield after two days. Azidation of **6** afforded diastereomerically pure 2-azido-aminoalcohol **8**, which could be quantitatively converted into diamino-alcohol *syn-9* by hydrogenation on Pd/C. At this stage, the relative configuration of *syn-9* could be verified by comparison of its ¹H NMR spectrum with the one of literature-known diamino-alcohol *anti-9.*²⁷ Additionally, treatment of bromo-aminoalcohol **6** with K₂CO₃ in acetonitrile led to *trans*-configured aziridine 7 in a yield of 81%.²⁸

CONCLUSION

In conclusion, we have developed a new method for the efficient synthesis of bromo-isoxazolidines by diastereoselective bromocyclization of *O*-allyl-*N*-tosyl-hydroxylamines, which are derived from easily available allylic alcohols. For this stereospecific process, highly substituted and cyclic alkenes can also be employed. The reaction presumably proceeds via an *N*-bromo intermediate, which leads to inter- or intramolecular, electrophilic activation of the alkene moiety. The utility of the new method was further exemplified by transformation of the bromo-isoxazolidines into 2-azido-aminoalcohols, diaminoalcohols, and aziridines.

EXPERIMENTAL SECTION

General Methods. All syntheses involving air- and moisturesensitive compounds were carried out using standard Schlenk-type glassware under an atmosphere of argon. Solvents were dried under argon using a commercial purification system. Unless stated otherwise all chemicals were used as supplied. $^1\!\dot{H}$ and $^{13}\!C$ NMR spectra were recorded at room temperature on commercial 400 and 500 MHz instruments. The chemical shift δ is given relative to TMS and referenced to the residual solvent signal. The attributions of the chemical shifts were determined by means of COSY, HSQC, HMQC, and NOE experiments. Melting points are not corrected. High resolution mass spectra (HRMS) were obtained with an ESI-TOF spectrometer. IR spectra were recorded using a NaCl disk (Film). Xray data sets were collected using a diffractometer using Mo K α radiation ($\lambda = 0.71073$ Å, graphite monochromator) at 133 K. For structure solution and refinement, the programs of the SHELXS-97 series were used.²⁹ All reactions were monitored by thin layer chromatography (TLC). Flash chromatography was carried out using silica gel (0.040-0.063 mm). N-Bromoacetamide (NBA),³⁰ bis(2,4,6

(1j),³³ cyclopent-1-en-1-ylmethanol (1k),³⁴ and (*E*)-4-phenylbut-3en-2-ol (1c)³⁵ were prepared according to literature procedures. (*Z*)-3-(2-Tolyl)prop-2-en-1-ol (1f)³⁶ was prepared by partial hydrogenation of the corresponding propargylic alcohol using Lindlar's catalyst³⁷ according to the reported method for (*Z*)-3-phenylprop-2-en-1-ol (1b)³⁸ with slight modifications.

General Procedure for the Preparation of O-Allyl-*N***-phthalimido-hydroxylamines (GP1).** A modified procedure by Saito²² was used: To a stirred solution of the allylic alcohol (1.0 equiv), triphenylphosphine (1.1 equiv), and *N*-hydroxyphthalimide (1.1 equiv) in tetrahydrofuran (0.25 M) diethyl azodicarboxylate (40% in toluene, 1.1 equiv) was added dropwise at 0 °C. After complete addition, the reaction was stirred at rt for the time given. The solvent was removed in vacuo, and the crude reaction mixture was purified by column chromatography on silica gel.

General Procedure for the Preparation of O-Allyl-N-tosylhydroxylamines (GP2). To a stirred solution of the O-allyl-Nphthalimido-hydroxylamine (1.0 equiv) in dichloromethane or tetrahydrofuran (0.25 M) hydrazine monohydrate (1.1 to 3.0 equiv) was added. The resulting suspension was stirred at rt until all starting material was gone (TLC), before water was added. The aqueous phase was extracted three times with dichloromethane, and the combined organic layers were washed with brine. After drying with sodium sulfate, filtration, and evaporation of the solvent, the crude product was directly used without further purification.

The crude material was suspended in dichloromethane (0.25 M), triethylamine (1.2 equiv), and *p*-TsCl (1.1 equiv) was added subsequently at rt. After reaction completion, as indicated by TLC analysis, water was added, and the aqueous phase was extracted three times with dichloromethane. The combined organic layers were washed with brine and dried over sodium sulfate. After filtration and evaporation of the solvent, the crude product was purified by column chromatography on silica gel.

General Procedure for the Bromocyclisation of O-Allyl-N-tosyl-hydroxylamines (GP3). To a solution of the O-allyl-N-tosyl-hydroxylamine (1.0 equiv) in dichloromethane (0.05 M) protected from light N-bromoacetamide (1.1 equiv) was added in one portion. The solution was stirred at rt until the reaction was complete, as indicated by TLC analysis. $Na_2S_2O_5$ -solution (10%) in water was added, and the aqueous layer was extracted three times with dichloromethane. The combined organic layers were washed with brine and dried over sodium sulfate. After filtration and evaporation of the solvent, the crude product was purified by column chromatography on silica gel.

(25) A solution of N-bromo-hydroxylamine derivative 5 in $CDCl_3$ was obtained by treatment of 3e with NBA (1.0 equiv) and rapid filtration over a plug of silica gel. Because of its instability (decomposition upon removal of the solvent or light exposure), it was characterized only by ¹H NMR, ¹³C NMR, and IR spectroscopy.
