Thermolysis of 3,4-cis ring-fused 5-spirocyclopropane isoxazolidines 16, 18–21, 33, 34, 38a, and **61**, in the presence of a protic acid at 70-110 °C, yielded 3,4-cis ring-fused azetidin-2-ones **22**-**26**, 41, 42, 46, and 62 with concomitant extrusion of ethylene, in good yields. So far, the collected evidences strongly support a mechanism started by a homolytic cleavage of the protonated N-Obond for the rearrangement of 5-spirocyclopropane isoxazolidines to  $\hat{\beta}$ -lactams. Some different competitive pathways can then follow depending on the stability or the stereoelectronic properties of cationic diradical intermediates. The two-step process, intramolecular 1,3-dipolar cycloaddition/ thermal rearrangement under acidic conditions, represents a general synthesis of a new class of 3,4-cis-fused bicyclic azetidin-2-ones starting from easily available compounds such as amino acids, hydroxy acids, and dicarbonyl or amino alcohol derivatives.

#### Introduction

5-Spirocyclopropane isoxazolidines **1** can be easily synthesized by 1,3-dipolar cycloaddition of nitrones and methylenecyclopropane derivatives<sup>1</sup> and are characterized by a unique reactivity caused by the presence of the strained three-membered ring spiro-fused on the adjacent position of the weak N–O bond. Isoxazolidines 1 undergo a thermally induced ring expansion to tetrahydropyridin-4-ones 4 through a homolytic cleavage of the N–O bond, followed by the opening of the cyclopropane ring and formation of the relatively more stable oxoethyl diradical 3. The intermediate 3 can then evolve to 4 by radical ring closure (Scheme 1).<sup>2,3</sup>

The temperature necessary to trigger the rearrangement in solution phase usually ranges from 110 to 180 °C, except for N-aryl-substituted 5-spirocyclopropane isoxazolidines which undergo the N-O cleavage also at room temperature.<sup>4</sup> The two-step process 1,3-dipolar cycloaddition/thermal rearrangement has been successfully applied to the synthesis of several selectively

#### **SCHEME 1**

substituted piperidines including indolizidine and quinolizidine alkaloids.<sup>1a,5</sup>

We report here a new specific behavior of 5-spirocyclopropane isoxazolidines 1. In particular, cycloadducts **1** can be selectively converted into  $\beta$ -lactam derivatives through ring contraction and concomitant extrusion of ethylene by heating at 70-110 °C in the presence of a protic acid.<sup>6</sup>

#### **Results and Discussion**

Recently, new tri- and tetracyclic spirocyclopropane isoxazolidines 8 were prepared starting from the 1-vinylcyclopropyl tosylate (5), which underwent Pd<sup>0</sup>-catalyzed nucleophilic substitution of  $\alpha$ -amino and  $\alpha$ -hydroxy

## **SCHEME 2**

acid derivatives to afford exclusively alkylidenecyclopropanes **6**. The esters **6** were easily converted into the corresponding nitrones **7** which spontaneously evolved to **8** (Scheme 2).<sup>7</sup>

Alternatively, the treatment of 5 with diethylzinc, in the presence of a catalytic amount of Pd<sup>0</sup>, afforded the zinc complex 11,<sup>8</sup> which underwent selective electrophilic addition of aldehyde 12 to give alkylidenecyclopropane 13. This process represents a nice example of "umpolung of reactivity"<sup>9</sup> for the synthesis of alkylidenecyclopropanes. After acetylation and hydrolysis of the acetal moiety, aldehyde 14 was treated with N-methylhydroxylamine to generate the alkylidenecyclopropane nitrone 15, which underwent intramolecular cycloaddition to give an equimolecular mixture of diastereomers exo-16a and endo-16b (Scheme 3).<sup>6b</sup> As in the previous examples,<sup>7</sup> the presence of the short three-atom chain between the two reacting sites affected the cycloaddition mode by disfavoring the formation of bridged regioisomeric cycloadducts.

The assignment of the relative configuration of adducts *exo*-**16a** and *endo*-**16b** was based on the <sup>1</sup>H NMR resonances of 5-H. In particular, 5-H in *exo*-**16a** ( $\delta = 5.28$  ppm, quintet, J = 4.7 Hz) has a downfield chemical shift with respect to the corresponding proton in *endo*-**16b** ( $\delta = 4.97$  ppm, quintet, J = 6.5 Hz) in accord with the more congested endo position. The structural assignment was confirmed by the analysis of the NOESY spectrum of *endo*-**16b** which exhibited a correlation between 5-H ( $\delta = 4.97$  ppm) and the hydrogen atoms of the bridge 3a-H ( $\delta = 2.87-2.75$  ppm) and 6a-H ( $\delta = 3.59-3.55$  ppm).

The adducts *exo-***8**, *exo-***16a**, and *endo-***16b** rearranged into the corresponding pyridones by simple heating in refluxing xylenes (Schemes 2 and 3). In particular, each adduct *exo-***8**<sup>7</sup> gave the *exo-***9** as a unique product. On the contrary, both isoxazolidines *exo-***16a** and *endo-***16b** were converted into a mixture of two diastereomeric pyridones *exo-***17a** and *endo-***17b** in a 5.4:1 ratio (63%) and a 1:5.5 ratio (26%), respectively. The epimerization at C-6 likely occurred during the rearrangement process as the isolated *exo-***17a** and *endo-***17b** did not interconvert under the rearrangement reaction conditions. In contrast to unsubstituted octahydro-1-methyl-4*H*-cyclopenta[*b*]pyrridin-4-one<sup>5f</sup> and some octahydro-1*H*-pyrrolo[3,4-*b*]pyri**SCHEME 3** 

**SCHEME 4** 

din-4-ones,<sup>10</sup> pyridones **17** do not seem to isomerize to the corresponding trans-fused compounds.

The thermal behavior of 5-spirocyclopropane isoxazolidines, after protonation, was completely different.<sup>6</sup> The enantiopure compounds *exo*-**18**–**20** and the racemic **21** in the presence of trifluoroacetic acid (TFA) underwent a clean reaction at 70–110 °C to afford 6-azabicyclo[3.2.0]heptan-7-ones **22–25** with conservation of the relative and absolute configuration (Scheme 4).<sup>6</sup> Under the same conditions, both *exo*-**16a** and *endo*-**16b** were converted into a diastereomeric mixture of *exo*-**26a** and *endo*-**26b** in a 1.6:1 ratio (96%) and a 1:2 ratio (82%), respectively.<sup>11</sup> Analogously to the products of the rearrangement in neutral conditions, such as *exo*-**17a** and *endo*-**17b**, both the isolated  $\beta$ -lactams *exo*-**26a** and *endo*-**26b** were stable under the reaction conditions. An explanation of this epimerization of acetates is not available at the moment.

<sup>(11)</sup> An equimolecular mixture of *exo*-**16a** and *endo*-**16b** was converted in equimolecular amounts of *exo*- and *endo*- $\beta$ -lactams in only 63% yield under the same reaction conditions (TFA, CH<sub>3</sub>CN, reflux temperature, 15 min).

**SCHEME 5** 

Compounds exo-22, exo-23, rac-25, exo-26a, and endo-26b could be easily purified and were obtained in fair yield after chromatography on silica gel. Unfortunately, the tricylic lactam exo-24 could be only partially purified by treatment with Dowex 50WX8-200 ion-exchange resin or by reversed-phase HPLC, although its structure could be fully determined by spectroscopical means.  $\beta$ -Lactams 22-25 and 26a,b were characterized by distinctive spectral data such as IR stretching ( $\nu_{CO} = 1740 - 1756$ cm<sup>-1</sup>) and <sup>13</sup>C NMR resonances ( $\delta_{CO} = 170.7 - 165.4$  ppm). Furthermore, the values of the coupling constants between vicinal C–H were consistent with the depicted stereochemistry (22, 23, 25, 26:  $H_1-H_5 J = 3.5-4.0 Hz$ ; **22**, **23**:  $H_4-H_5 J = 0$  Hz; **24**:  $H_{2a}-H_{6a} J = 3.9$  Hz and  $H_{2a}$ - $H_{2b}$  J = 0 Hz). The optical purity of **22** and **23** was ascertained by <sup>1</sup>H NMR analysis in the presence of increasing amount of Eu(hfc)<sub>3</sub>.

Finally, the exact structure of the C<sub>2</sub> fragment, eliminated in the acid-induced reorganization of 5-spirocyclopropane isoxazolidines, was unequivocally established by analyzing the <sup>1</sup>H NMR spectra of the CD<sub>3</sub>CN solution of protonated **18–21** after heating at 70 °C. In particular, the presence of the intense singlet at 5.41 ppm, besides the  $\beta$ -lactam **22–25** signal set, was a clear evidence of ethylene formation during the reaction.

The same strategy previously used to prepare the spirofused isoxazolidines 18-21 was applied to the syntheses of their superior homologues 33, 34, and 38a,b, starting from the anthranilic acid derivatives 27 [Z = 2-nitrobenzenesulfonyl (Ns)], 28 [Z = Tosyl (Ts)], and the amino alcohol 35, respectively (Scheme 5).

The Pd<sup>0</sup>-catalyzed nucleophilic substitution of 5 occurred either with 27, 28, or 35 with complete regio-

selectivity and in good yields (64-98%). In the last case, the use of a tertiary amine as a base allowed to carry out the reaction in the presence of the unprotected hydroxyl group. The alkylidenecyclopropanes 29, 30, and 36 were converted into the corresponding aldehydes 31, 32, and 37 and then treated with N-methylhydroxylamine to generate the nitrone moiety, which underwent the intramolecular 1,3-dipolar cycloaddition. The cisfused cycloadducts 33 and 34 were obtained at 110 °C in high yields (90-91%) and with complete control of regioand stereochemistry. The nitrone derived from 37 reacted at room temperature and produced a mixture of adducts 38a,b and the bridged-regioisomer 39 in 8:3:1 ratio and 59% overall yield (Scheme 5). Major compound 38a was assigned the cis ring fusion on the basis of the bridged hydrogen coupling constant value ( $J_{H-H} = 4.6$  Hz compared to  $J_{\rm H-H} = 11.4$  for **38b**). The higher selectivity showed by the aromatic compounds can be ascribed to the lower flexibility inferred by the aromatic ring to the four-atom chain linking the two reactive sites.

The thermal behavior of 5-spirocyclopropane isoxazolidines **33**, **34**, and **38a**,**b** was studied either in neutral and acidic conditions.

The adducts **33** and **34** failed to give pyridones **40** by heating (Scheme 6) up to 120 °C where they proved to be stable, but decomposed at higher temperatures. On the contrary, the cis- and trans-fused isoxazolidines **38a** and **38b** underwent the usual rearrangement by heating in refluxing xylenes, and both afforded the thermodynamically more stable trans-fused bicyclic ketone **45** in 40 and 38% yield, respectively (Scheme 7).

A rather different behavior was observed in acidic conditions. The tetracyclic isoxazolidines **33** and **34** underwent a clean reaction at 110 °C in the presence of a small excess of TFA. Under these conditions, the cis-fused  $\beta$ -lactams **41** and **42** were obtained in good yields (60–72%) by ring contraction and loss of ethylene (Scheme 6). The same reaction occurred by heating **33** and **34** in toluene in the presence of *p*-toluenesulfonic acid (TsOH) or in refluxing ethanol with HCl or on treating directly the aldehydes **31** and **32** with MeNHOH·HCl in refluxing ethanol in absence of triethylamine. It has to be stressed that all these reactions had to be carried out in strictly anhydrous conditions; otherwise, a 2:1 mixture of  $\beta$ -lactams **41**, **42** and ethyl ketones **43**, **44** were obtained when traces of H<sub>2</sub>O were present.

The structures of **41** and **42** were unambiguously established as for **22–25** and **26a**,**b** from spectroscopic

# SCHEME 7

data. Especially diagnostic were IR stretching  $\nu_{\rm CO}$  (1750 and 1752 cm<sup>-1</sup> for **41** and for **42**, respectively), <sup>13</sup>C NMR resonances  $\delta_{\rm CO}$  (166.2 and 166.9 ppm for **41** and for **42**, respectively), and <sup>1</sup>H NMR resonances of H<sub>8b</sub> ( $\delta$  = 4.45 ppm, d, J = 5.1 Hz for **41** and  $\delta$  = 4.29 ppm, d, J = 5.1 Hz for **42**).

The two isomeric cis- and trans-fused isoxazolidines 38a and 38b showed a different thermal behavior in the presence of TFA. In particular, the cis isomer 38a was converted into the corresponding  $\beta$ -lactam **46** in high yields (87%) (46:  $\delta_{CO} = 168.3 \text{ ppm}; \nu_{CO} = 1754 \text{ cm}^{-1}$ ), while the isomer **38b** failed to give the more strained trans-fused bicyclic azetidin-2-one and underwent a different rearrangement to a new ketone to which the structure of 1,6-naphthyridinone 47 was assigned (Scheme 7). The bicyclic ketone 47 is clearly a structural isomer of 45, the rearrangement product in neutral conditions, with a methyl group shifted from N-1 (in 45) to C-3 (in 47). Compound 47 was recovered as a TFA salt after chromatography on silica gel, and the <sup>1</sup>H NMR spectrum showed the  $\alpha$ -carbonyl protons of 47·TFA were lacking probably for a rapid keto-enolic exchange under the acidic conditions. The free ketone 47 could be obtained by treatment with a basic ion-exchange resin. The synthesis of the trideuteriomethyl derivative **38b-d**<sub>3</sub><sup>12</sup> allowed us to establish that the N-methyl group of 38b becomes the 2-methylene in 47 (Scheme 8). In fact, the <sup>1</sup>H NMR spectra of 47·TFA and 47-d<sub>2</sub>·TFA were analogous except for the resonances corresponding to the two H atoms on C-2 ( $\delta$ : 3.07 ppm, br s) which were not present in the spectrum of the deuterated compound. The new and unexpected behavior of the protonated transfused bicyclic 5-spirocyclopropane isoxazolidine 38b provided a significant piece of information for the elucidation of the mechanism of  $\beta$ -lactam formation (see below).

**SCHEME 9** 

In a preliminary attempt to rationalize the mechanism of  $\beta$ -lactam formation from 5-spirocyclopropane isoxazolidines **1**, the possible involvement of piperidin-4-ones **4**, as reaction intermediates, was examined and discarded when proved that they are stable under the acidic rearrangement conditions.

The protonation of the isoxazolidine nitrogen atom, unequivocally demonstrated by the significant downfield shift of signals in the <sup>1</sup>H NMR spectra of adducts **1** in the presence of protic acids, must be the initial step of the formation of  $\beta$ -lactams **53**. The protonated isoxazolidine **48**, then, undergoes a thermally induced cleavage of the weak protonated N–O bond that might occur either in a homo- (Scheme 9, path A) or in a heterolytic (Scheme 9, path B) mode.

In the first hypothesis,<sup>13</sup> the diradical cation **49** could evolve to the relatively more stable ionic diradical **50**, in analogy to the process in neutral condition. The lack of any trace of tetrahydropyridones in acidic conditions could be explained by the formation of a strong intramolecular hydrogen bond in **50** that should prevent the radical ring closure to piperidone **52**. At the same time,

<sup>(12)</sup> **38b-d<sub>3</sub>** was obtained starting from aldehyde **37** and CD<sub>3</sub>NHOH and following the same procedure used for the synthesis of **38b**.

<sup>(13)</sup> This hypothesis recalls the first step of the Hoffman Loffler Freitag reaction that is the thermal induced homolysis of N–X bond in the presence of strong protic acid, where X is a chlorine or bromine atom: (a) Corey, E. J.; Hertler, W. R. J. Am. Chem. Soc. **1960**, 82, 1657–1668. (b) Wolff, M. E. Chem. Rev. **1963**, 63, 55–64. (c) Stella, L. Angew. Chem., Int. Ed. Engl. **1983**, 22, 337–350.

the hydrogen bond might keep the nitrogen and C=O group close enough and with the correct orbital overlapping required for the closure of a four-membered ring with formation of a N–CO bond. Finally, the  $\beta$ -lactam **53** could be formed from **51** by radical fragmentation and deprotonation (path A).

In the second hypothesis, the heterolysis of the N–O bond could be assisted by the concomitant C3–C4 ring expansion of a cyclopropyloxonium ion in analogy with the cyclopropylcarbinyl cation behavior. The formed oxetane cation **55** might be intramolecularly trapped by nitrogen to form a highly strained oxaazaspiroheptane **56**. This strained intermediate could evolve to **53** and ethylene through a formal retro Paternò–Buchi reaction and deprotonation (path B).

The different behaviors of the cis- and trans-fused isoxazolidines **38a** and **38b** appear to be in accord with the illustrated diradical pathway. In the cis-intermediate **57**, the relative orientation of the orbitals is suitable for the attack of the radical nitrogen to the carbonyl as shown diagrammatically in Scheme 10. In the trans-intermediate **59**, there is an unfavorable stereoelectronic orientation for the overlapping of nitrogen and C=O orbitals. This fact should cause a relatively longer lifetime for the diradical cation **59** which undergoes different reaction pathways. The diradical **59**, via intra- or intermolecular H-shift, could give rise to the iminium ion **60** which is exactly the expected precursor of ketone **47** via an intramolecular Mannich reaction (Scheme 10).

The formation of an iminium intermediate can also explain the formation of ethyl ketones 43 and 44 in the presence of traces of H<sub>2</sub>O. Hydrogen bonding with molecules of H<sub>2</sub>O destabilizes the intramolecular hydrogen bond in the intermediates 65 and 66 hampering the four-membered ring closure (Scheme 11). Therefore, the diradical cations 67 and 68 could evolve to the iminium ions 69 and 70, respectively, analogues of 60. The  $\beta$ -iminium ketones **69** and **70** preferentially undergo either elimination to 43, or hydrolysis to aldehydes 63 and 64 and the corresponding amine, which successively produces 43 by a retro-Michael addition. A confirmation of this hypothesis came by treating the aldehyde 31 with a slight excess of N-benzylhydroxylamine chlorhydrate in absolute ethanol (ca. 99.8%) (Scheme 11). After 3 h at the reflux temperature the reaction mixture consisted of the  $\beta$ -lactam **62**, the ethyl ketone **43**, benzaldehyde (**64**), and a small amount of N-benzyl-C-phenyl nitrone derived from the condensation of benzaldehyde with the excess of hydroxylamine.

Finally, more support for the proposed homolytic mechanism derived from the study of the rearrangement of the spirocyclopropane isoxazolidines **71**. At room

**SCHEME 12** 

temperature and in the presence of TsOH, the mixture of isoxazolidines **71** provided a complex mixture of the  $\beta$ -lactam **73**,<sup>14</sup> styrene (**74**), the *cis*- and *trans*-quinolizidinones **75**<sup>15</sup> (trans/cis ratio 2:1), and the enone **76**<sup>16</sup> which slowly underwent intramolecular cyclization to **75** (Scheme 12).

The formation of all the observed products can be rationalized starting from the common diradical intermediate **72** which could evolve to the  $\beta$ -lactam **73** and styrene (**74**) through ring closure and fragmentation (Scheme 9, path A), but the relatively more stable benzyl radical could also undergo an 1,5-hydrogen shift to give, after deprotonation, the conjugated enone **76**.

## Conclusion

A novel chemoselective reaction of 5-spirocyclopropane isoxazolidines has been reported. These compounds can selectively undergo ring contraction to  $\beta$ -lactams, with concurrent extrusion of ethylene, or ring expansion to tetrahydropyridones, depending on the preliminary treatment with or without a protic acid.

The two-step process 1,3-dipolar cycloaddition/acidic thermal rearrangement represents a useful strategy to

<sup>(14)</sup> Brunwin, D. M.; Lowe, G.; Parker, J. J. Chem. Soc. C 1971, 3756–3762.

<sup>(15)</sup> The diastereomeric mixture of 5-spirocyclopropane isoxazolidines **71** was converted into the *cis*- and *trans*-quinolizidinones **76** in 28% and 52% isolated yield, respectively, by heating at 110 °C under neutral conditions.

<sup>(16)</sup> Quick, J.; Meltz, C. J. Org. Chem. 1979, 44, 573-578.

synthesize new classes of 3,4-cis-fused bicyclic azetidin-2-ones, starting from easily available alkylidenecyclopropanes obtained from  $\alpha$ -amino or  $\alpha$ -hydroxy acids, 1,3dicarbonyl,  $\beta$ -amino alcohol, and acid derivatives.

Two different hypotheses have been formulated to rationalize the formation of  $\beta$ -lactam and ethylene, but the formation of transient cation diradical intermediates from the homolytic cleavage of the protonated N–O bond was shown to be consistent with the observed behavior of 5-spirocyclopropane isoxazolidines under acidic conditions.

## **Experimental Section**

**General Remarks.** All the reactions requiring anhydrous conditions were carried out under nitrogen or argon, and the solvents were appropriately dried before use. NMR spectra were recorded in CDCl<sub>3</sub> (except were indicated), and the data are reported in  $\delta$  (ppm) from TMS. Multiplicity of the <sup>13</sup>C NMR was determined by means of APT experiments. In mass spectra, relative percentages are shown in brackets.  $R_f$  values refer to TLC on 0.25 mm silica gel plates and were measured (except were indicated) using the same eluant employed in the purification of the corresponding compounds.

**5-Cyclopropylidene-1,1-diethoxy-3-pentanol (13).** A mixture of  $Pd(OAc)_2$  (11.2 mg, 5% mol) and  $PPh_3$  (31.4 mg, 12% mol) was degassed under reduced pressure for 1 h. Then THF (5 mL) was added under Ar, and the solution was stirred for 5 min. A solution of **5** (286 mg, 1.2 mmol) in THF (5 mL) was added, and when the solution had turned green, a solution of aldehyde **12** (146.2 mg, 1 mmol) in THF (5 mL) was added. After the mixture was stirred for 5 min, diethylzinc (224 mg, 2 mmol) was added and the mixture was stirred at rt for 3 h. The mixture was quenched with a 6 M solution of  $NH_4Cl/NH_4$ -OH (2 mL) and filtered through Celite and  $Na_2SO_4$ . The solvent was removed under reduced pressure, and the crude **13** was purified by chromatography on silica gel (CH<sub>2</sub>Cl<sub>2</sub>/diethyl ether 9:1) to obtain **13** as a colorless oil (135 mg, 63%).

**13:**  $R_f = 0.38$ ; <sup>1</sup>H NMR (250 MHz)  $\delta$  5.70 (m, 1H), 4.65 (t, J = 5.7 Hz, 1H), 3.38 (m, 1H), 3.67–3.42 (m, 4H), 3.13 (d, J = 2.4 Hz, 1H), 2.30 (m, 2H), 1.74–1.68 (m, 2H), 1.15 (t, J = 7.1 Hz, 6H), 0.98 (m, 4H); <sup>13</sup>C NMR (66 MHz)  $\delta$  124.2 (s), 114.0 (d), 102.0 (d), 68.1 (d), 62.0 (t), 61.2 (t), 39.6 (t), 15.2 (q), 15.1 (q), 2.5 (t), 1.6 (t); MS (EI) m/z 213 (0.08), 101 (68), 75 (37), 73 (90), 45 (100).

**3-(Acetyloxy)-5-cyclopropylidenepentanal (14). (1) Acetylation of the Hydroxyl Group.** Acetic anhydride (55  $\mu$ L, 0.59 mmol) was added dropwise at 0 °C to a solution of the alcohol **13** (1.76 g, 8.2 mmol) and DMAP (53 mg, 0.43 mmol) in diethyl ether (2 mL). The solution was stirred at rt for 1.5 h. The resulting mixture was concentrated under reduced pressure, diluted with hexane, filtered through a sintered glass funnel, and concentrated. After purification of the crude mixture by chromatography on silica gel (pentane/ diethyl ether 8:2), the acetyl derivative was obtained as a colorless oil (1.77 g, 84%).

**3**-(Acetyloxy)-5-cyclopropylidene-1,1-diethoxypentane:  $R_i = 0.43$ ; <sup>1</sup>H NMR (200 MHz)  $\delta$  5.70 (tp, J = 7.1, 2.1Hz, 1H), 5.08 (quintet, J = 6.2 Hz, 1H), 4.54 (t, J = 5.9 Hz, 1H), 3.60 (m, 2H), 3.48 (m, 2H), 2.44 (t, J = 6.4 Hz, 2H), 2.01 (s, 3H), 1.86 (t, J = 6.0 Hz, 2H), 1.18 (t, J = 7.1 Hz, 6H), 1.03 (m, 4H); <sup>13</sup>C NMR (66 MHz)  $\delta$  170.4 (s), 125.0 (s), 112.8 (d), 100.3 (d), 70.9 (d), 61.7 (t), 61.0 (t), 37.8 (t), 36.8 (t), 21.2 (q), 15.3 (q), 15.2 (q), 2.7 (t), 1.8 (t); IR (CDCl<sub>3</sub>)  $\nu$  2977, 2930, 1739 cm<sup>-1</sup>; MS (EI) m/z 213 (0.1), 103 (55), 96 (15), 79 (13), 75 (29), 43 (100); MS (CI with NH<sub>3</sub>) m/z 274 (1, MNH<sub>4</sub><sup>+</sup>), 211 (100).

(2) Deprotection of the Aldehyde. A 0.2 M aqueous solution of  $H_2SO_4$  (100 mL) was added to a solution of the acetal (1.77 g, 6.9 mmol) in THF (80 mL) at rt. The mixture was stirred for 7 h, and then diethyl ether (80 mL) was added.

The two phases were separated, and the organic layer was washed sequentially with a saturated solution of NaHCO<sub>3</sub> and a saturated solution of NaCl. The resulting crude product was purified by chromatography on silica gel (pentane/diethyl ether 75:25). Aldehyde **14** was obtained as a colorless oil (905 mg, 72%).

**14:**  $R_f = 0.25$ ; <sup>1</sup>H NMR (200 MHz)  $\delta$  9.73 (t, J = 2.2 Hz, 1H), 5.70 (tp, J = 7.1, 2.1 Hz, 1H), 5.39 (quintet, J = 6.2 Hz, 1H), 2.64 (dd, J = 6.2, 2.2 Hz, 2H), 2.55–2.43 (m, 2H), 2.01 (s, 3H), 1.13–0.98 (m, 4H); <sup>13</sup>C NMR (66 MHz)  $\delta$  199.5 (d), 170.3 (s), 126.4 (s), 112.0 (d), 68.9 (d), 47.4 (t), 36.4 (t), 21.1 (q), 2.8 (t), 1.9 (t); IR (CDCl<sub>3</sub>)  $\nu$  2981, 1734 cm<sup>-1</sup>; MS (CI with NH<sub>3</sub>) m/z 200 (71, MNH<sub>4</sub><sup>+</sup>), 183 (100, MH<sup>+</sup>), 182 (34, M<sup>+</sup>), 140 (60), 123 (92).

(3a $R^*$ ,5 $R^*$ ,6a $S^*$ )- and (3a $R^*$ ,5 $S^*$ ,6a $S^*$ )-1,3a,4,5,6,6a-Hexahydro-1-methylspiro[3*H*-cyclopent[*c*]isoxazole-3,1'cyclopropan]-5-yl Acetate (16a and 16b). *N*-Methylhydroxylamine hydrochloride (468 mg, 5.6 mmol) and pyridine (453  $\mu$ L, 5.6 mmol) were added to a solution of the aldehyde 14 (850 mg, 4.7 mmol) in diethyl ether (235 mL) at rt. The mixture was stirred at rt overnight, and the salts were eliminated by filtration through a short pad of Celite. The solvent was removed under reduced pressure, and the crude mixture (16a/ 16b = 1:1) was separated by chromatography on silica gel (pentane/diethyl ether 25:75) to obtain 16a as a colorless oil (379 mg, 32%) and 16b as a colorless oil (379 mg, 32%).

(1*R*\*,6*R*\*)-5,5,7-Trimethyl-3-(methylphenyl)-3,7-diazabicyclo[4.2.0]octan-8-one (46). TFA (31  $\mu$ L, 0.40 mmol) was added to a solution of the adduct **38a** (59 mg, 0.20 mmol) in toluene (5 mL) at rt. The mixture was refluxed for 2 h. Evaporation of the solvent and purification of the crude product by chromatography on silica gel ( $CH_2Cl_2/MeOH$  30:1) gave **46** (47 mg, 87%) as a colorless oil.

**46:**  $R_f = 0.31$ ; <sup>1</sup>H NMR (200 MHz)  $\delta$  7.54–7.37 (m, 5H), 4.37 (A part of an AB system, J = 12.4 Hz, 1H) 4.24 (B part of an AB system, J = 12.8 Hz, 1H), 3.74–3.57 (m, 1H), 3.57–3.44 (m, 2H), 3.40–3.24 (m, 1H), 3.32 (A part of an AB system, J = 12.6 Hz, 1H), 2.95 (s, 3H), 2.86 (B part of an AB system, J = 12.6 Hz, 1H), 1.19 (s, 3H), 1.10 (s, 3H); <sup>13</sup>C NMR (50 MHz)  $\delta$  168.3 (s), 131.1 (d, 2C), 130.1 (d), 129.3 (d, 2C), 128.5 (s), 62.5 (t), 58.4 (q), 54.8 (t), 44.9 (d), 41.5 (t), 34.2 (s), 30.3 (d), 25.4 (q), 24.0 (q); MS (70 eV) m/z 258 (1, M<sup>+</sup>), 174 (16), 167 (8), 139 (15), 124 (81), 120 (35), 91 (100), 69 (30); IR (CDCl<sub>3</sub>)  $\nu$  2975, 2931, 1754, 1663, 1420, 1189 cm<sup>-1</sup>; HRMS found 281.16295, C<sub>16</sub>H<sub>22</sub>N<sub>2</sub>NaO required 281.16298.

(4a*R*\*,8a*R*\*)-Octahydro-3,8,8-trimethyl-6-(methylphenyl)[1,6]naphthyridin-4(1*H*)-one (47). TFA (18  $\mu$ L, 0.24 mmol) was added to a solution of **38b** (33 mg, 0.12 mmol) in toluene (3 mL) at rt and under nitrogen atmosphere The mixture was refluxed for 2 h 45 min. Evaporation of the solvent and purification by chromatography on silica gel (MeOH + 1% NH<sub>3</sub>) gave the 1,6-naphthyridine 47·TFA (18 mg, 58%) as TFA salt. After treatment with Ambersep 900 OH ion-exchange resin and purification by chromatography on silica gel (petroleum ether/ethyl acetate + 1% TEA 1:1), the ketone 47 (13 mg, 40%) was obtained as a colorless oil.

**47**•**TFA:** <sup>1</sup>H NMR (400 MHz, CD<sub>3</sub>CN)  $\delta$  7.54–7.47 (m, 5H), 4.81 (d, J = 12.0 Hz, 1H), 4.37 (A part of an AB system, J = 12.8 Hz, 1H), 4.16 (B part of an AB system, J = 12.8 Hz, 1H), 3.86 (dm, J = 9.3 Hz, 1H), 3.75 (tm, J = 10.5 Hz, 1H), 3.17 (br t, J = 112.2 Hz, 1H), 3.07 (br s, 2H), 3.02–2.95 (m, 2H), 1.51 (s, 3H), 1.21 (s, 3H), 0.95 (s, 3H).
