Supporting Information

ABSTRACT: Methanol solutions of iridium(III) tetra(*p*-sulfonatophenyl)porphyrin [(TSPP)Ir^{III}] form an equilibrium distribution of methanol and methoxide complexes ([(TSPP)Ir^{III}(CD₃OD)_(2-n)(OCD₃)_n]⁽³⁺ⁿ⁾⁻). Reaction of [(TSPP)Ir^{III} with dihydrogen (D₂) in methanol produces an iridium hydride [(TSPP)Ir^{III}–D(CD₃OD)]⁴⁻ in equilibrium with an iridium(I) complex [(TSPP)Ir^I(CD₃OD)]⁵⁻. The acid dissociation constant of the iridium hydride (Ir–D) in methanol at 298 K is 3.5 × 10⁻¹². The iridium(I) complex [(TSPP)Ir^I(CD₃OD)]⁵⁻ catalyzes reaction of [(TSPP)Ir^{III}–D(CD₃OD)]⁴⁻ with CD₃–OD to produce an iridium methyl complex [(TSPP)Ir^{III}–CD₃(CD₃OD)]⁴⁻ and D₂O. Reactions of the iridium hydride with ethene and propene produce iridium alkyl complexes, but the Ir–D complex fails to give observable addition with acetaldehyde and carbon monoxide in methanol. Reaction of the iridium hydride with propene forms both the isopropyl and propyl complexes with free energy changes (ΔG° 298 K) of –1.3 and –0.4 kcal mol⁻¹ respectively. Equilibrium thermodynamics and reactivity studies are used in discussing relative Ir–D, Ir–OCD₃ and Ir–CD₂ bond energetics in methanol.

INTRODUCTION

Application of water and methanol as both solvent media and reactants is an important direction for organometallic catalysis research.^{1–27} Current interest in group nine metallocporphyrin reactivity and catalysis studies in this area has been focused on the behavior of complexes with sulfonated porphyrin ligands in water^{5,6,8,18–23,28} and methanol.^{16,28} Water and methanol are high dielectric constant liquids^{29,30} that have both hydrogen bonding and donor capability, which results in many analogous features. Methanol is distinguished by having both hydroxylic and hydrocarbon components which result in the unusual property of miscibility in both water and organic hydrocarbon solvents.

Rhodium porphyrins have a more highly developed reaction chemistry in diverse media^{16,18–23,31–60} compared to iridium porphyrins.^{18,61–74} This Article reports on reactivity and thermodynamic studies for methanol solutions of tetra(*p*-sulfonatophenyl)porphyrin iridium(III) methanol and methoxide complexes ([(TSPP)Ir^{III}(CD₃OD)_(2-n)(OCD₃)_n]⁽³⁺ⁿ⁾⁻). The Ir(III) complex reacts with H₂(D₂) to form an iridium hydride complex ([(TSPP)Ir^{III}–D(CD₃OD)]⁴⁻) that has an Ir–D acid dissociation constant of 3.5 × 10⁻¹² in methanol. The Ir–D complex reacts with CD₃OD in basic methanol by a net CD₃–OD bond cleavage to form an iridium methyl complex ([(TSPP)Ir^{III}–CD₃(CD₃OD)]⁴⁻) and D₂O. Alkenes react with [(TSPP)Ir^{III}–D(CD₃OD)]⁴⁻ to form iridium alkyl complexes, but CO reacts to form only a carbon monoxide

adduct[(TSPP)Ir–D(CO)]⁴⁻ without observation of an iridium formyl species (Ir–CHO). Results from equilibrium thermodynamic and reactivity studies are used in discussing relative Ir–D, Ir–OCD₃ and Ir–CD₂ bond energetics in methanol.

RESULTS AND DISCUSSION

Methanol and Methoxide Complexes of (TSPP)Ir^{III} in CD₃OD. Dissolution of iridium(III) tetra(*p*-sulfonatophenyl)porphyrin (Na₃[(TSPP)Ir^{III}(CD₃OD)₂]·18CD₃OD) in CD₃OD results in a pH dependent equilibrium distribution of a bis-methanol complex [(TSPP)Ir(CD₃OD)₂]³⁻ (1) with mono- and bis-methoxide complexes [(TSPP)Ir(OCH₃)(CD₃OD)]⁴⁻ (2) and [(TSPP)Ir(OCD₃)₂]⁵⁻ (3) (eqs 1 and 2) (Figure 1). The axially coordinated methanol and methoxide ligands for 1, 2 and 3 in methanol rapidly exchange protons with the bulk methanol (298 K) (Figure 1), which results in a single mole fraction averaged pyrrole ¹H NMR resonance for 1, 2 and 3 (Figures 2 and 3).

Figure 1. Methanol and methoxide complexes of (TSPP)Ir^{III} in methanol.

The ¹H NMR of the bis-methanol complex **1** and bis-methoxide complex **3** can be directly obtained at limiting high and low hydrogen ion concentrations respectively. The mole fraction averaged pyrrole ¹H NMR resonances for equilibrium distributions of **1**, **2** and **3** as a function of [D⁺] were used in determining the acid dissociation constants for coordinated methanol by nonlinear least-squares curve fitting to the expression

$$\delta_{2,3,4(\text{obs})}(\text{pyr}) = (K_1 K_2 \delta_3(\text{pyr}) + K_1 [\text{D}^+] \delta_2(\text{pyr}) + [\text{D}^+]^2 \delta_1(\text{pyr})) / (K_1 K_2 + K_1 [\text{D}^+] + [\text{D}^+]^2)$$

giving $K_1(298\text{K}) = 2.3 \times 10^{-8}$, $K_2(298\text{K}) = 2.1 \times 10^{-11}$ and $\delta_2(\text{pyr}) = 8.61$ ppm; **1** $[(\text{TSPP})\text{Ir}^{\text{III}}(\text{CD}_3\text{OD})_2]^{3-}$ is $\delta_1(\text{pyr}) = 8.76$ ppm, and **3** $[(\text{TSPP})\text{Ir}^{\text{III}}(\text{OCD}_3)_2]^{5-}$ is $\delta_3(\text{pyr}) = 8.43$

Figure 3. Observed limiting fast proton exchange mole fraction averaged pyrrole ¹H NMR shifts for (TSPP)Ir^{III} complexes **1**, **2** and **3** in CD₃OD as a function of pD. Triangular points are experimentally observed pyrrole shift values in methanol, and the line is calculated for $K_1(298\text{K}) = 2.3 \times 10^{-8}$ and $K_2(298\text{K}) = 2.1 \times 10^{-11}$.

ppm (Figure 3). The coordinated methanol acid dissociation constants for $[(\text{TSPP})\text{Ir}(\text{CD}_3\text{OD})_2]^{3-}$ at 298 K ($K_1 = 2.3 \times 10^{-8}$, $K_2 = 2.1 \times 10^{-11}$) in methanol (Table 1) are similar to the values for the coordinated water acid dissociation constants in D₂O at 298 K for $[(\text{TSPP})\text{Ir}(\text{D}_2\text{O})_2]^{3-}$ ($K_1(\text{D}_2\text{O}) = 4.8 \times 10^{-8}$, $K_2(\text{D}_2\text{O}) = 2.6 \times 10^{-11}$).⁸

Reaction of Hydrogen (H₂/D₂) with [(TSPP)-Ir^{III}(CD₃OD)₂]³⁻ in CD₃OD. Methanol solutions of $[(\text{TSPP})\text{Ir}^{\text{III}}(\text{CD}_3\text{OD})_2]^{3-}$ at pD lower than 10 react with hydrogen ($P(\text{H}_2/\text{D}_2) \sim 0.4\text{--}0.9$ atm) in CD₃OD to form a hydride (deuteride) complex $[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$ (**4**) (eq 3, Figure 4). Acidic solutions of the iridium hydride complex $[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$ in a mixture of CH₃OH/CD₃OD

Figure 2. Mole fraction averaged ¹H NMR (500 MHz) porphyrin pyrrole singlet and phenyl AB pattern for complexes **1**, **2** and **3** in CD₃OD ($T = 298$ K): (A) pD = 4.0, (B) pD = 8.5 and (C) pD = 11.5.

Table 1. Equilibrium Thermodynamic Values for [(TSPP)Ir] Reactions in Methanol ($T = 298\text{ K}$)^a

(TSPP)Ir reactions	K	ΔG°
$[(\text{TSPP})\text{Ir}^{\text{III}}(\text{CD}_3\text{OD})_2]^{3-} \rightleftharpoons [(\text{TSPP})\text{Ir}^{\text{III}}(\text{OCD}_3)(\text{CD}_3\text{OD})]^{4-} + \text{D}^+$	2.3×10^{-8}	+10.4
$[(\text{TSPP})\text{Ir}^{\text{III}}(\text{OCD}_3)(\text{CD}_3\text{OD})]^{4-} \rightleftharpoons [(\text{TSPP})\text{Ir}^{\text{III}}(\text{OCD}_3)_2]^{5-} + \text{D}^+$	2.1×10^{-11}	+14.6
$[(\text{TSPP})\text{Ir}^{\text{III}}(\text{CD}_3\text{OD})_2]^{3-} + \text{D}_2 \rightleftharpoons [(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-} + \text{D}^+ + \text{CD}_3\text{OD}$	4.5	-0.8
$[(\text{TSPP})\text{Ir}(\text{OCD}_3)(\text{CD}_3\text{OD})]^{4-} + \text{D}_2 \rightleftharpoons [(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-} + \text{CD}_3\text{OD}$	1.9×10^8	-11.2
$[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-} \rightleftharpoons [(\text{TSPP})\text{Ir}^{\text{I}}(\text{CD}_3\text{OD})]^{5-} + \text{D}^+$	3.5×10^{-12}	+15.6
$[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-} + \text{C}_2\text{H}_4 \rightleftharpoons [(\text{TSPP})\text{Ir}-\text{CH}_2\text{CH}_2\text{D}(\text{CD}_3\text{OD})]^{4-}$	63	-2.5
$[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-} + \text{C}_3\text{H}_6 \rightleftharpoons [(\text{TSPP})\text{Ir}-\text{CH}(\text{CH}_3\text{D})\text{CH}_3(\text{CD}_3\text{OD})]^{4-}$	9.2	-1.3
$[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-} + \text{C}_3\text{H}_6 \rightleftharpoons [(\text{TSPP})\text{Ir}-\text{CH}_2\text{CHDCH}_3(\text{CD}_3\text{OD})]^{4-}$	2.0	-0.4

^a $\text{CD}_3\text{OD} \rightleftharpoons \text{D}^+ + \text{OCD}_3^-$; $K = 2.0 \times 10^{-17}$; $\Delta G^\circ = 22.8\text{ kcal mol}^{-1}$.

were used to observe the high field iridium hydride resonance at -59.1 ppm.

Reaction 3 was permitted to equilibrate for a period of two weeks at 298 K before determination of the equilibrium constant by integration of the ^1H NMR for **2** and **4** and measurement of the solution pH ($K_3(298\text{K}) = 4.5(0.5)$; $\Delta G^\circ_3 = -0.8(0.1)\text{ kcal mol}^{-1}$) (Table 1). The equilibrium constant for the reaction of dihydrogen with $[(\text{TSPP})\text{Ir}(\text{OCD}_3)(\text{CD}_3\text{OD})]^{4-}$ (**2**) (eq 4) is too large for direct evaluation by ^1H NMR, but the free energy change for reaction 4 can be derived from the measured ΔG° values for reactions 1 and 3 (Scheme 1, $\Delta G_4^\circ = \Delta G_3^\circ - \Delta G_1^\circ$; $\Delta G_4^\circ(298\text{K}) = -11.2\text{ kcal mol}^{-1}$).

Acid Dissociation Constant of $[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$ in Methanol. The iridium hydride complex $[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$ (**4**) in methanol occurs in a ^1H NMR observable equilibrium with the iridium(I) derivative $[(\text{TSPP})\text{Ir}^{\text{I}}(\text{CD}_3\text{OD})]^{5-}$ (**5**) (eq 5) in the pD range of 10.5–11.5.

Proton exchange between **4** and **5** at 298 K in methanol solution is sufficiently slow to permit observation of separate although slightly broadened porphyrin pyrrole hydrogen resonances for **4** and **5**.

Evaluation of the ^1H NMR integrated intensities for the pyrrole hydrogens of **4** and **5** along with the deuterium ion concentration were used in determining the acid dissociation constant for the deuteride complex ($[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$) in methanol ($K_5(298\text{K}) = 3.5(0.2) \times 10^{-12}$; $\Delta G^\circ(298\text{K}) = 15.6(0.1)\text{ kcal mol}^{-1}$) (Table 1). The acid dissociation constant for **4** in methanol ($K_5(298\text{K}) = 3.5 \times 10^{-12}$) is slightly larger than the value for $[(\text{TMPS})\text{Ir}-\text{D}(\text{D}_2\text{O})]^{8-}$ in water ($K(298\text{K}) = 1.8 \times 10^{-12}$)⁷² and much smaller than the acid dissociation constants for an analogous rhodium complex $[(\text{TSPP})\text{Rh}-\text{D}(\text{CD}_3\text{OD})]^{4-}$ in methanol ($K(298\text{K}) = 1.1 \times 10^{-9}$; $\Delta G^\circ(298\text{K}) = 12.2\text{ kcal mol}^{-1}$)⁷ and $[(\text{TSPP})\text{Rh}-\text{D}(\text{D}_2\text{O})]^{4-}$ in water ($K(298\text{K}) = 8.0 \times 10^{-8}$; $\Delta G^\circ(298\text{K}) = 9.7\text{ kcal mol}^{-1}$) (Figure 5).²²

The iridium(I) complex ($[(\text{TSPP})\text{Ir}^{\text{I}}(\text{CD}_3\text{OD})]^{5-}$ (**5**)) reacts as a nucleophile with methyl iodide (CH_3I) in methanol to form the methyl complex ($[(\text{TSPP})\text{Ir}-\text{CH}_3(\text{CD}_3\text{OD})]^{4-}$ (**6**)), which is readily identified in solution by the characteristic high field methyl ^1H NMR resonance ($\delta = -7.15\text{ ppm}$) (Supporting Information). Addition of triphenyl phosphite to the methanol solution of the methyl complex (**6**) produces the phosphite complex, which is readily detected in methanol solution by $^{31}\text{P}-\text{CH}_3$ coupling ($\delta = -7.37\text{ ppm}$, 15 Hz) between the trans phosphite and methyl groups in $[(\text{TSPP})\text{Ir}-\text{CH}_3(\text{P}(\text{OC}_6\text{H}_5)_3)]^{4-}$ (Supporting Information).

Reduction of Ir(III) to Ir(I) by Methanol. Methanol solutions of $[(\text{TSPP})\text{Ir}^{\text{III}}(\text{OCD}_3)_2]^{5-}$ (**3**) (pD > 11) are kinetically stable for days at 298 K, but upon warming to 343 K the $(\text{TSPP})\text{Ir}^{\text{III}}$ is quickly reduced to $[(\text{TSPP})\text{Ir}^{\text{I}}(\text{CD}_3\text{OD})]^{5-}$ (**5**) and methanol is oxidized to formaldehyde (Scheme 2).

Iridium(III) porphyrins are thus only metastable reagents for substrate reactions in strongly basic methanol. Oxidation of methanol becomes catalytic through quantitative dioxygen oxidation of $(\text{TSPP})\text{Ir}^{\text{I}}$ to $(\text{TSPP})\text{Ir}^{\text{III}}$ (Scheme 2), and formaldehyde oxidizes further under these conditions to formate. The methanol oxidation to formaldehyde is currently viewed as occurring by an intermolecular $\beta\text{ C-H}$ deprotonation of methoxide coordinated to Ir(III) in the basic high

**Figure 4.** ^1H NMR (500 MHz, CD_3OD , pD = 4.8). Equilibrium among $[(\text{TSPP})\text{Ir}^{\text{III}}(\text{CD}_3\text{OD})_2]^{3-}$, H_2 and $[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$.

Scheme 1. Thermodynamic Cycle for D₂ Reaction with [(TSPP)Ir(OCD₃)(CD₃OD)]⁴⁻

$$\Delta G_4^\circ = \Delta G_3^\circ - \Delta G_1^\circ = -11.2 \text{ kcal mol}^{-1}$$

Figure 5. Acid dissociation constant for [(TSPP)Ir-D(CD₃OD)]⁴⁻ in CD₃OD from [(TSPP)Ir^I(CD₃OD)]⁵⁻ in equilibrium with the [(TSPP)Ir-D(CD₃OD)]⁴⁻ as a function of pD from ¹H NMR. Nonlinear least-squares fit gives $K_5(298\text{K}) = 3.5 \times 10^{-12}$.

dielectric medium. Fast quantitative air oxidation of iridium(I) to iridium(III) is an important feature of the iridium porphyrin system that permits iridium(III) porphyrins to function as oxidation catalysts by directly using O₂ without the need for a cocatalyst.

Reaction of [(TSPP)Ir-D(CD₃OD)]⁴⁻ with CD₃OD To Form [(TSPP)Ir-CH₃(CD₃OD)]⁴⁻ and Water Catalyzed by [(TSPP)Ir^I(CD₃OD)]⁵⁻ in Methanol. Methanol solutions that contain only the hydride [(TSPP)Ir-D(CD₃OD)]⁴⁻ (4) (pD < 10.5) or the iridium(I) complex [(TSPP)Ir^I(CD₃OD)]⁵⁻ (5) (pD > 12.0) are kinetically stable over periods of months. When the pD is in the range of 10.8–11.8 the iridium hydride complex [(TSPP)Ir-D(CD₃OD)]⁴⁻ (4) is observed to react with methanol to form the methyl complex [(TSPP)Ir-CH₃(CD₃OD)]⁴⁻ (6) and water (eq 6). Formation of an iridium–methyl complex from reaction with methanol was first reported by Chan.¹⁸ Reaction 6 in CH₃–OH results in formation of [(TSPP)Ir-CH₃(CH₃OH)]⁴⁻, which is easily observed in solution by the characteristic high field methyl resonance in the ¹H NMR spectrum ($\delta_{\text{Ir-CH}_3} = -7.15$).

Formation of the [(TSPP)Ir-CD₃(CD₃OD)]⁴⁻ complex only occurs at a finite rate in the pD range (10.8–11.8) where both [(TSPP)Ir-D(CD₃OD)]⁴⁻ (4) and [(TSPP)-

Ir^I(CD₃OD)]⁵⁻ (5) occur at ¹H NMR observable concentrations. The net process corresponds to reaction of the hydride (4) with CD₃OD to form the methyl complex (6) and D₂O (eq 6) where [(TSPP)Ir^I(CD₃OD)]⁵⁻ (5) functions as a catalyst. The proposed reaction pathway is illustrated in Scheme 3. This process is an unusual example of CD₃–OD bond cleavage which is driven thermodynamically by formation of water.

Scheme 3. Reaction of [(TSPP)Ir-D(CD₃OD)]⁴⁻ and CD₃OD To Form [(TSPP)Ir-CD₃(CD₃OD)]⁴⁻ and Water Catalyzed by [(TSPP)Ir^I(CD₃OD)]⁵⁻ in Methanol

Reaction of [(TSPP)Ir-D(CD₃OD)]⁴⁻ with Alkenes in CD₃OD. Methanol (CD₃OD) solutions of the iridium hydride complex 4 [(TSPP)Ir-D(CD₃OD)]⁴⁻ (1 × 10⁻³ M) in vacuum adapted NMR tubes were pressurized with ethene, propene, 1-pentene and 1-hexene gases each at 100 Torr pressure, and changes in the ¹H NMR spectra were followed over a period of days. The ¹H NMR spectra for CD₃OD solutions of 4 with ethene and propene showed the appearance of the characteristic high field porphyrin ring current shifted resonances for metallocporphyrin alkyl complexes ((por)M–R), but the longer chain alkenes did not produce ¹H NMR observable concentrations of organoiridium porphyrin species.

Reaction of [(TSPP)Ir-D(CD₃OD)]⁴⁻ with ethene produces the iridium ethyl complex [(TSPP)Ir-CH₂CH₂D-(CD₃OD)]⁴⁻ (7), which is identified in methanol solution by the high field region of the ¹H NMR (–1.85 (br, 2H, –CH₂) and –5.68 (br, 2H, –CH₂D) (eq 7). Equilibrium concn-

Scheme 2. Proposed Pathway for Methanol Reduction of Iridium(III) Porphyrins at High pD

trations of the iridium ethyl complex $[(\text{TSPP})\text{Ir}-\text{CH}_2\text{CH}_2\text{D}(\text{CD}_3\text{OD})]^{4-}$, $[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$ and ethene determined by integration of the ^1H NMR were used in evaluating the equilibrium constant for reaction 7 at 298 K ($K_7 = 63$ and $\Delta G_7^\circ = -2.5 \text{ kcal mol}^{-1}$) (Table 1). Addition of the $(\text{TSPP})\text{Ir}-\text{D}$ to ethene in methanol ($\Delta G_7^\circ = -2.5 \text{ kcal mol}^{-1}$) is similar to that for the reaction of ethene with $(\text{TMPS})\text{Ir}-\text{D}$ in water ($\Delta G^\circ = -3.7 \text{ kcal mol}^{-1}$).⁷²

The reaction of $[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$ with propene results in observation of an equilibrium distribution of two isomers. The major isomer corresponds to the iridium isopropyl complex $[(\text{TSPP})\text{Ir}-\text{CH}(\text{CH}_2\text{D})\text{CH}_3(\text{CD}_3\text{OD})]^{4-}$ (8) which is identified in solution by distinct doublets at -2.20 ppm ($-\text{CH}(\text{CH}_2\text{D})\text{CH}_3$) and a broad peak at -6.33 ppm ($-\text{CH}(\text{CH}_2\text{D})\text{CH}_3$) (eq 8). The minor isomer is the iridium *n*-propyl derivative $[(\text{TSPP})\text{Ir}-\text{CH}_2\text{CHDCH}_3(\text{CD}_3\text{OD})]^{4-}$ (9), which is identified by the distinctive high field resonances for the iridium propyl complex at -1.70 ppm ($-\text{CH}_2\text{CHDCH}_3$), -3.01 ppm ($-\text{CH}_2\text{CHDCH}_3$) and -5.82 ppm ($-\text{CH}_2\text{CHDCH}_3$) (eq 9). Equilibrium constants and ΔG° values for reactions 8 and 9 were evaluated at 298 K by ^1H NMR ($K_8 = 9.2(0.2)$, $\Delta G_8^\circ = -1.3 \text{ kcal mol}^{-1}$; $K_9 = 2.0(0.5)$, $\Delta G_9^\circ = -0.4 \text{ kcal mol}^{-1}$) (Table 1).

Thermodynamic preference for the Ir–D addition with propene to give the Markovnikov regioisomer is opposite to that observed for propene reactions with $(\text{TMPS})\text{Ir}-\text{D}$ in water⁷² and with $(\text{TSPP})\text{Rh}-\text{D}$ and $(\text{TMPS})\text{Rh}-\text{D}$ complexes in water and methanol (Scheme 4).^{20,22} Repulsive steric

Scheme 4. Addition Reactions of Propene with $[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$ in Methanol

interactions favor placing the metalloporphyrin on a primary carbon, but M–C covalent bonding is maximized by placing the metal center on a secondary carbon which better stabilizes the negative charge.⁷⁵ The increased importance of covalent bonding compared to rhodium and the smaller steric requirements of TSPP compared to TMPS may combine in the $(\text{TPPS})\text{Ir}-\text{D}$ system to alter the regioselective addition with propene. The small free energy change in the addition reaction of propene with **4** to produce $[(\text{TSPP})\text{Ir}-\text{CH}_2\text{CHDCH}_3(\text{CD}_3\text{OD})]^{4-}$ ($\Delta G_9^\circ = -0.4 \text{ kcal mol}^{-1}$) compared to related Rh–D reaction in water ($\sim -5 \text{ kcal mol}^{-1}$) results in part from the previously recognized increase in the difference between the Ir–D and Ir–CH₂ BDFEs compared to the Rh–D and Rh–CH₂ BDFE values.

Reaction of $[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$ with CO in CD₃OD in Methanol. The hydride complex $[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$ (**4**) does not react with CO ($P_{\text{CO}} = 700 \text{ Torr}$) in methanol to form an iridium formyl complex ($[(\text{TSPP})\text{Ir}-\text{CDO}(\text{CD}_3\text{OD})]^{4-}$), but simply produces a trans hydrido carbonyl adduct ($[(\text{TSPP})\text{Ir}-\text{D}(\text{CO})]^{4-}$ (**10**)) (eq 10). The inability to obtain observable quantities of an iridium formyl complex contrasts with rhodium porphyrin hydrides where reaction with CO ($P_{\text{CO}} < 1 \text{ atm}$) to produce metallo–formyl complexes is a prominent characteristic reaction in benzene,^{36,76} water²⁷ and methanol.¹⁷

An increase in the Ir–H relative to the Ir–C is consistent with the inability of the iridium hydride complex (**4**) to produce observable quantities of the α -hydroxyethyl complex ($[(\text{TSPP})\text{Ir}-\text{CH}(\text{OD})\text{CH}_3(\text{CD}_3\text{OD})]^{4-}$), which is a thermodynamically favorable reaction of the corresponding rhodium porphyrin system.⁴²

Difference between the Bond Dissociation Free Energy of Ir–OCD₃ and Ir–D for $[(\text{TSPP})\text{Ir}-\text{X}(\text{CD}_3\text{OD})]^{4-}$ Complexes in CD₃OD. The difference between the $[(\text{TSPP})\text{Ir}-\text{OCH}_3]$ and $[(\text{TSPP})\text{Ir}-\text{D}]$ units can be estimated as shown from analysis of the bonds breaking and forming as derived from eq 4 (Scheme 5).

The iridium hydride $[(\text{TSPP})\text{Ir}-\text{D}(\text{CD}_3\text{OD})]^{4-}$ (**4**) bond dissociation free energy (BDFE) is larger than the iridium methoxide BDFE for $[(\text{TSPP})\text{Ir}(\text{OCD}_3)(\text{CD}_3\text{OD})]^{4-}$ (**2**) in methanol by $13.3 \text{ kcal mol}^{-1}$ ($[\text{Ir}-\text{D}] - [\text{Ir}-\text{OCH}_3] = 13.3 \text{ kcal mol}^{-1}$). The iridium hydroxide BDFE is $3.6 \text{ kcal mol}^{-1}$ larger than the iridium hydride BDFE ($[\text{Ir}-\text{OD}] - [\text{Ir}-\text{D}] = 3.6 \text{ kcal mol}^{-1}$) for the similar $(\text{TMPS})\text{Ir}$ complexes in water,⁷² which places the Ir–OH BDFE in water at $\sim 17 \text{ kcal mol}^{-1}$ larger than the Ir–OCH₃ BDFE in methanol. The difference of 14 kcal mol^{-1} in H–OCH₃ and H–OH bond dissociation energies⁷⁷ is dominated by the difference in the radical stabilization energies of the methoxy and hydroxyl radicals,

Scheme 5. BDFE of $[(\text{Ir}-\text{OCD}_3)-(\text{Ir}-\text{D})]$ Derived from the Reaction of $[\text{Ir}-\text{OCD}_3(\text{CD}_3\text{OD})]^{4-}$ and D₂

and this term also dominates the difference in the Ir–OCD₃ and Ir–OD bond dissociation free energies.

SUMMARY AND CONCLUSIONS

Solutions of iridium(III) tetrakis(*p*-sulfonatophenyl)porphyrin [(TSPP)Ir^{III}] in methanol form a hydrogen ion dependent equilibrium distribution between three species [(TSPP)Ir(CD₃OD)₂]^{3–}, [(TSPP)Ir(OCD₃)(CD₃OD)]^{4–} and [(TSPP)Ir(OCD₃)₂]^{5–}. The coordinated CD₃OD acid dissociation constants for [(TSPP)Ir(CD₃OD)₂]^{3–} are $K_1 = 2.3 \times 10^{-8}$ and $K_2 = 2.1 \times 10^{-11}$, which are somewhat smaller than those of [(TSPP)Ir(D₂O)₂]^{3–} in water ($K_1(\text{H}_2\text{O}) = 4.8 \times 10^{-8}$, $K_2(\text{H}_2\text{O}) = 2.6 \times 10^{-11}$). Reaction of [(TSPP)Ir^{III}] species in CD₃OD with dihydrogen (H₂/D₂) results in formation of an iridium hydride complex [(TSPP)Ir–D(CD₃OD)]^{4–} with an equilibrium constant of $K_3 = 4.5$, $\Delta G^\circ(298\text{K}) = -0.8$ kcal mol^{–1}, which is smaller than the corresponding reaction of [(TSPP)Rh^{III}] in methanol ($K = 1.0 \times 10^3$, $\Delta G^\circ(298\text{K}) = -4.1$ kcal mol^{–1}). The less favorable ΔG° for the (TSPP)Ir^{III} compared to (TSPP)Rh^{III} system results from larger Ir–methanol binding compared to Rh–methanol that more than compensates for the increase in metal hydride bond energy ($[(\text{Ir}-(\text{CD}_3\text{OD}) - [\text{Rh}(\text{CD}_3\text{OD})]) > ([\text{Ir}-\text{D}] - [\text{Rh}-\text{D}])$). The acid dissociation constant for [(TSPP)Ir–D(CD₃OD)]^{4–} measured in methanol is 3.5×10^{-12} ($\Delta G^\circ(298\text{K}) = 15.6$ kcal mol^{–1}) and is comparable to that for [(TMPS)Ir–D(D₂O)]^{8–} in water ($K = 1.8 \times 10^{-12}$, $\Delta G^\circ(298\text{K}) = 16.0$ kcal mol^{–1}) and much smaller than that for [(TSPP)Rh–D(CD₃OD)]^{8–} in methanol ($K = 1.1 \times 10^{-9}$) which primarily reflects the larger Ir–D bond energy. The Ir(I) complex [(TSPP)Ir(I)–(CD₃OD)]^{5–} in the pD range of 10.8 to 11.8 is observed to catalyze reaction of the iridium hydride [(TSPP)Ir–D(CD₃OD)]^{4–} with methanol to form an Ir–CH₃ complex [(TSPP)Ir–CD₃(CD₃OD)]^{4–} and water. This thermodynamically favorable CD₃–OD bond cleavage occurs at a significant rate only in the pD range where both the Ir–D and Ir(I) have substantial equilibrium concentrations which maximize the opportunity for a concerted process.
